The report tabulates a remarkable series of figures showing the progress made in the last ten years. In 1927 in-patients admitted numbered 33,407, out-patient attendances were 1,457,706, and 3,445 operations were performed; the respective figures for 1936 were 96,081, 6,500,441, and 11,229. A serious epidemic of cerebro-spinal meningitis occurred during the first half of the year under review, involving more than 13,000 cases and over 9,000 deaths. The provinces of Darfur and Kordofan suffered most heavily. In Khartoum province there were 360 cases with 251 deaths, a case mortality rate of 69.7 per cent. It is recorded that two-thirds of the cases were in males, of whom the majority were engaged in arduous manual labour. General prophylactic measures in this province were successful in keeping the epidemic within bounds until the advent of the first rains secured its termination. Refugees from Abyssinia introduced small-pox into frontier districts of the Blue Nile province in August. Owing to the inaccessibility of this region during the rainy season it was difficult to deal promptly with the outbreak; 501 cases with 132 deaths were reported. It is stated, however, that, owing to a coincident epidemic of chicken-pox, differential diagnosis was a matter of difficulty in some cases for the subordinate medical staff stationed in the area. The incidence of malaria, which still constitutes the most important public health problem in the Sudan, assumed almost epidemic proportions in parts of Merowe, Dongola, and Wadi Halfa districts, climatic and other factors favouring the breeding of mosquitos. A permanent increase in the sanitary service in these districts is deemed necessary in order to prevent a repetition of the outbreak. There were thirty-eight cases of blackwater fever during the year, with fourteen deaths; the majority were Sudanese-Arabs; British cases numbered three, one of which was fatal. From Omdurman a number of cases of mercury poisoning were recorded. In the instance of one man, who died, mercury was recovered from his organs, and it was discovered that he had been treating himself for gonorrhoea with intra-urethral instillations of native butter (semn). A sample of the semn proved to be contaminated with mercury. Analysis of samples from all parts of the country pointed to an origin of contamination in the Western Sudan. It transpired that semn producers in that region were using drums which had previously contained abavit, a preparation containing mercury biniodide and mercury perchloride, used as a seed dressing. One drum was found still to contain traces of mercury. Measures were immediately taken to seize and destroy all empty abavit drums, and semn producers were warned against their use. As a result no further contamination was discovered and no further cases of mercury poisoning were reported.

The Secretary of the British Medical Association receives requests to appoint delegates to various conferences which take place in the summer months. He would be glad to have early information regarding proposed visits by members to places abroad this year.

THE NEW INSULINS

THIRD LETTSOMIAN LECTURE

The third and concluding Lettsomian Lecture was delivered by Dr. GEORGE GRAHAM before the Medical Society of London on March 7, the subject of the lecture being the new insulins. The first two lectures were reported in the *Journal* of March 5 (p. 529) and March 12 (p. 579).

The new insulins, said Dr. Graham, had been available only for a short time, one of them for two years and the other for one year, and he himself had certainly not had enough experience to be dogmatic as to their value. His conclusions were for the moment tentative. Insulin when first introduced in 1922-3 was a very crude product, with certain impurities which had no value for the treatment of diabetes. Later the ordinary insulin became far purer. Nevertheless, the number of patients whom it seemed difficult to control had become greater. It had been suggested that this was due to a change in the insulin, the older insulin having a slower action than the newer.

The problem of looking after these difficult cases had been dealt with in various ways. The late Dr. Otto Leyton gave a mixed oil and insulin, which, however, was somewhat painful; others had tried a mixture of insulin and adrenaline, and others, again, a mixture of insulin and pituitrin. Then came the modification devised by Hagedorn of protamine insulin, an insulin being produced which was insoluble and had a much slower action than the ordinary product. Scott in Toronto, who had already found that zinc was always present in the pancreas, added zinc to protamine insulin, so that now there were three insulins on the market: first, the ordinary insulin; secondly, the protamine insulin of Hagedorn, known as "insulin retard"; and, thirdly, the insulin introduced by Scott and Fisher in the form of zinc-protamine-insulin. Hagedorn's insulin had been in use for two years, zinc-protamine-insulin for only one. The former had to be given, as a rule, in two doses, zinc-protamine-insulin could very often be given in one, which was a great advantage as many patients disliked the two injections.

Overdose

Dr. Graham devoted most of his remaining time to showing a series of case charts and discussing them. In most of these cases he had started with two doses of ordinary insulin a day, and then introduced a certain number of units of one of the newer insulins. Most often he used a mixture of ordinary soluble insulin and zinc-protamine-insulin. In a certain number of cases he had been able to do away altogether with the ordinary insulin and to use only the zinc preparation. He dealt at some length with the question of overdose. When protamine insulin was introduced it was said that patients would notice the signs of overdose very much better, because the blood sugar would go down more slowly, and they would have time to recognize that something was the matter and to take sugar. But he found that some of his patients who did not recognize their signs of overdose were no better off with zinc-protamine-insulin. He had heard of some who when put on zinc-protamine-insulin suffered very severe overdosing, although in fact that had not happened among his own patients. But he did not think the new insulins were any better in this respect than the old.

The great advantage was the ability to give the day's injection in one dose. Hagedorn originally introduced his insulin for difficult cases, and in a number of such patients, whose case sheets he exhibited, Dr. Graham had found the product of value. A mixture of ordinary and "retard" had proved very useful indeed. He showed three cases of failure of control, the patients having their overdose soon after breakfast and feeling very miserable,

but by a judicious working in of the new preparation with the old it had been possible to restore them to a happier condition. Among child patients especially the "retard" made them much better, easier to look after, and less irritable.

At first he thought the slow-acting insulin never acted in quite the same way two days running. But since then he had looked up a number of patients who had had only ordinary insulin and had found the same fluctuations if the patient had his diabetes well under control. Therefore he had come round to the view that it was not the failure to absorb the insoluble product which gave rise to the erratic sugar curve, but that the fault lay with the severity or type of diabetes. Some patients raised objections to the new insulin, saying that with ordinary insulin they knew when to expect their overdose; others refused to change because it would disarrange their habit of life, and others again were disinclined to try anything new. Nevertheless, he thought the new insulins were of great value for the mild cases especially, and he hoped that by a blend of insulins, using the slow-acting and the quick-acting together, control of the difficult cases might be obtained.

The fifteen years' experience of treatment of diabetes which had been the general subject of his lectures had been a most interesting period in which to work, and he felt increasingly what a debt of gratitude was due to Banting and Best.

A vote of thanks to Dr. Graham for his lectures was accorded on the motion of Sir WILLIAM WILLCOX, seconded by Dr. E. R. CULLINAN. The subject of the new insulins was also discussed at the Royal Society of Medicine on March 8, and a report appears in this issue (page 637).

FRANCIS AMORY SEPTENNIAL PRIZE

In compliance with the requirements of a gift under the will of the late Francis Amory of Beverly, Massachusetts, the American Academy of Arts and Sciences announces the offer of a septennial prize for outstanding work with reference to the alleviation or cure of diseases affecting the human genital organs, to be known as the Francis Amory Septennial Prize. The gift provides a fund the income of which may be awarded for conspicuously meritorious contributions to the field of knowledge "during the said septennial period next preceding any award thereof, through experiment, study, or otherwise . . . in the diseases of the human sexual generative organs in general." The prize may be awarded to any individual or individuals for work of "extraordinary or exceptional merit" in this field.

In case there is work of a quality to warrant it, the first award will be made in 1940. The total amount of the prize will exceed ten thousand dollars, and may be given in one or more awards. It rests solely within the discretion of the Academy whether an award shall be made at the end of any given seven-year period, and also whether on any occasion the prize shall be awarded to more than a single individual.

While there will be no formal nominations, and no formal essays or treatises will be required, the committee invites suggestions, which should be made to the Amory Fund Committee, c/o The American Academy of Arts and Sciences, 28, Newbury Street, Boston, Massachusetts, U.S.A.

Sir Ashley Mackintosh, Extra Physician to His Majesty's Household in Scotland, who died on October 14, 1937, left personal estate in Great Britain valued at £24,590. After a few personal legacies he left his property, subject to a life interest, as to seven-fifteenths to Aberdeen University for the study of medicine; five-fifteenths to Aberdeen Joint Hospitals Fund; and one-fifteenth each to Aberdeen Maternity Hospital, Aberdeen Sick Children's Hospital, and Dr. Barnardo's Homes.

of tension for the shortest period possible are the points to observe to avoid this complication.

Another method of attack is advised by Chitty (1936). After the preliminary tourniquet the area is infiltrated with novocain, and, if the body is opaque to x rays, then under the fluorescent screen a hypodermic needle is inserted into the tissues guided by the history and the radiographs, probing until its point touches the foreign body. The light is turned on, the part incised along the needle, and the object located. In some cases it is an advantage to use two needles, directing the shafts approximately at right angles to each other, and on localization the incision is made between them.

In spite of these aids the operator may fail to detect the foreign body; then with the uncovered sterilized finger palpation of the wound tissues is helpful: the naked finger is more sensitive than the rubber-gloved hand. In the buttock, however, the meshes of connective tissue are dense; they feel hard and grate almost like a foreign body, so that in this situation digital palpation is of limited value. Despite its usefulness digital palpation is not the method of choice in seeking foreign bodies in a wound, although admittedly it is sometimes necessary under the x-ray screen. Wounds from which foreign bodies have been removed should be but loosely closed; a drain is often advisable, and always so if sepsis is apparent.

Fish-hooks and Crochet Needles

A fish-hook or crochet needle usually only partly penetrates a finger or hand. In such a case the part should be disinfected, anaesthetized by 1 per cent. novocain or 1 in 1,000 pantocaine, and the article grasped and pushed (not pulled) so that it emerges through the skin, which is snicked where the head presents. The bulbous or barbed extremity—for example, a crochet needle—is pressed on until the head protrudes; it is then cut off with wire-cutting forceps or pliers and the stump withdrawn. Incision or set operation is rarely necessary.

Sewing-machine Needles

A finger may be trapped by a sewing-machine needle, which passes through the nail, the phalanx, and the pulp of the finger; then, by a combination of bending and snatching away of the hand, the needle breaks. In this event the pulp of the finger should be anaesthetized and the finger pressed hard down on to a metal plate; the point of the needle is thus forced to retrace its path through the bone, and the fractured end appears under the nail. A little manipulation or enlargement of the hole of entry suffices for the needle to be seized with an artery forceps and extracted.

Miscellaneous Objects

Many foreign bodies—for example, wood, glass, aluminium, clothing, fish-bones, etc.—are not opaque to x rays. They are often associated with a wound which, whether a foreign body is suspected or not, should be treated as if it were infected, carefully explored, probed, and if necessary extended, the contused tissue being excised. Lacerations containing or suspected of containing glass require detailed search, as the sharp fragments travel unexpected distances. This surgical treatment will locate articles and missiles known and unknown, and it avoids infection and complications.

Occasionally a wound containing glass or a splinter will heal; a capsule of fibrous tissue forms around it, and no further trouble may be experienced. On the other

hand, the area may become painful to touch, causing the patient to seek advice. If the discomfort is constant and a nodule is palpable, exploration of the part is indicated. Glass fragments and needles are not as a rule heavily infected, and wounds containing them often heal by first intention. Lacerations contaminated with wooden splinters, metal filings, fish-bones, and pieces of clothing usually suppurate. All wounds below the knee, including superficial abrasions, must be given prophylactic anti-tetanic serum.

Gravel Rash

In cases where the foreign particles have not been removed, gravel rash of the face and hands heals with a disfiguring scar, which is only corrected by an extensive plastic operation; consequently every effort should be made to extract the whole of the foreign matter early after the injury. Under an anaesthetic the wound must be assiduously cleansed—this requiring considerable time—but not sutured, and compresses of 12 per cent. sodium sulphate should be applied four-hourly until healing is complete. The hypertonic action of these applications encourages extrusion of possible remaining particles; but their extraction is essentially the surgeon's responsibility, and demands patience, resource, and resolution.

Splinters

Splinters, if visible, are easily recovered by forceps, unless the wood is rotten, when the incision must be enlarged to allow of complete extraction. Metal filings are often oily and infected. In addition to scrupulous cleansing the wound must not be sutured, and a drain should be inserted.

Pellets

Pellets from air-guns and sporting guns are met with in civil hospital practice. Less often the plug of a blank cartridge may cause a wound. Although this paper is not intended to include these types of injury, two essentials are worthy of mention. The first is that the wound should never be closed after removal of the foreign body even though a joint be involved; and the second, that anti-tetanic serum should always be given.

ROYAL MEDICAL BENEVOLENT FUND

At a recent meeting of the committee three annuities and thirty-four grants were awarded. The total amount voted was £995.

One of the recipients was a doctor who is quite unable to practise owing to paralysis. He is married and has one child of school age. His grant was renewed for the fifth year in succession. The following letter has been received in acknowledgment:

"It has not been possible owing to my paralysis for me to write to you before, but now I have a typewriting machine on which I can tap with one finger of my left hand. It gives me great pleasure to address you personally. I am truly grateful for all the Fund has done in the past and is doing at the present time on my behalf. The Fund is truly a marvellous society. I do not like to think what our position would be without your magnificent help. I beg to convey my own and my family's most sincere thanks to the Committee."

Subscriptions and donations are urgently needed, and may be sent to the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, Cavendish Square, London, W.1.

Reports of Societies

THE VALUE OF ZINC-PROTAMINE-INSULIN

At a meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine on March 8 a discussion took place on the value of zinc-protamine-insulin in the treatment of diabetes.

Dr. R. D. LAWRENCE said that as a result of some work on the protamine insulin known as "insulin retard" two years ago he had suggested that insulin was secreted in two ways—namely, a small continuous secretion to control the carbohydrate metabolism, especially from endogenous sources of sugar, all the time, and an added secretion of insulin after a carbohydrate meal to deal with the augmented intake of carbohydrate substance. Since then his further work on the new insulin had confirmed that view. The ideal insulin preparation to reproduce normal function would have two actions: a slow and continuous one and a short and rapid one. That was asking a great deal of any preparation. There were now three insulins available: the old quickly acting type, the original Hagedorn preparation known as "insulin retard," and the more slowly acting preparation in which a small amount of zinc was added to the protamine preparation. Dr. Lawrence exhibited the following table to show how these insulins acted (in adults):

	Units	Duration (hours)	Hypoglycaemia commonly at	Type of Action
Soluble	10	4-6	2-4 hours	Quick and strong, balances carb. but little meals
	20	6-8	3-5	
	30-40	10-12	4-9	
"Retard"	10	8-10	4-6 hours	Slower and weaker, balancing less carb. hydrate
	20	12-16	6-9	
	40	18-24	7-12	
Zinc-protamine	10	6-8	4-5 hours	Very slow and weak, balances carbohydrate poorly
	20	12-14	8-12	
	30	18-24	16-24	

Unless the treatment with these new preparations could be brought down to one dose a day there was not a great advantage in the new insulin over the old. He had not been in a hurry to give the new preparations to patients who were having two doses of soluble insulin a day. Nevertheless, in the mild insulin case it was a great advantage to give 20 units of the zinc-protamine-insulin in one daily dose before breakfast. This was a great blessing to the general practitioner. His patient had to have insulin only once a day, a more liberal diet was allowed, and the general health remained excellent. With the more severe type of diabetes, the patient who would act for twenty-four hours, but many patients, especially young people and children, were so insulin-sensitive that it was impossible to treat them on one dose a day.

Rate of Action of Insulin

Dr. R. AITKEN said that the larger doses of zinc-protamine would exert their effect not only for twenty-four but for forty-eight or even sixty hours. The duration was not constant for a given dose for all patients; it varied somewhat from patient to patient. He wondered whether during that prolonged action insulin was being absorbed from the depot into which it was injected at the rate of so many units per hour, or whether the rate of absorption, and therefore the rate of action of insulin in the metabolism of the body, was greater during the earlier part of the time and tailed off towards the end. One would expect the latter, but it was a little difficult to get a convincing proof. It was likely, to judge from his case-

sheets, that these doses of zinc-protamine-insulin reached the peak of their activity quite soon after being given. They did not, of course, produce hypoglycaemia quite soon after being given, but there were other factors which determined the time when hypoglycaemia arose. If it were granted that the maximum activity was developed soon and diminished progressively, little diagrammatic pictures could be made of the daily course.

Dr. E. P. POULTON was not sure that Dr. Lawrence had been quite fair with regard to "insulin retard." In a communication to the Association of Physicians last summer it was stated that protamine insulin—Hagedorn's preparation—lasted nearly as long as zinc-protamine-insulin, while that might not be true, protamine insulin was, as regards time, an intermediate product between the soluble and the zinc-protamine-insulin. He had on occasion used the three insulins together. As regards changing from one to the other, he related a striking case of a woman who had a severe increase of her diabetes as a result of pregnancy, and had first been put on three doses a day, afterwards she was put on two doses of protamine-insulin, about 100 units a day. When the zinc-protamine-insulin was substituted the daily dose came down to 40 or 50, and for many months now she had remained on that basis of dosage, and was doing better than with the three doses of soluble insulin or the two doses of "retard."

Dr. GEORGE GRAHAM said that he was inclined at the moment to use a mixture of ordinary or soluble insulin and zinc-protamine-insulin. Only in a certain number of cases had he been able to do away altogether with the soluble insulin and use only zinc-protamine. In a number of cases he had used a mixture of ordinary and "retard," giving 50 units of "retard" in the morning and 20 or 30 units of ordinary at night, and in three cases he had an effect quite unexpected in the way of overdose, but an effect favourable on the whole to that combination. Dr. W. W. PAYNE said that in some cases in which he had used "retard" he had found great variation. One could not predict in any given subject which type of insulin was the best to use. One was less liable to get severe hypoglycaemic reactions on "retard" insulin than on the zinc-protamine, so that if he could find a formula with "retard" insulin which was satisfactory he preferred to use it. Unfortunately in children who became absolute diabetics, requiring something like 100 units a day, it was very difficult to get the required balance, but he had been successful in such cases in keeping a reasonable balance with just one dose of 100 units of zinc-protamine-insulin. With these newer insulins there were variations in some cases from day to day, but often patients, in spite of this inconvenience, refused to go back to soluble insulin, saying they were so much more comfortable on the one-dose-a-day method.

Dr. LAWRENCE did not approve of the "blunderbuss" method mentioned by Dr. Poulton of giving the three types of insulin together. It had not appealed to him from what he had seen of the results. One was dealing with at least two irregular forms of insulin, and their respective irregularities did not cancel one another out but more or less added together, and he had found the most enormous variations in experiments he had made with that method.

Vegetable Proteins for Diabetes

At the same meeting Dr. W. W. PAYNE brought forward a short communication on the use of some vegetable proteins in the treatment of diabetes. The subject was to have been developed at that meeting by the late Dr. Otto Leyton. Dr. Payne spoke in particular of the protein preparation called "profarin," said to be derived from locust beans. His trials with this substance so far, which had appertained only to diabetic children, were inconclusive, but when it was added to the basic diet a number of cases had been found in which there was no increase

SAFEGUARDING WATER SUPPLIES

MINISTER'S ADVICE TO LOCAL AUTHORITIES

The Minister of Health, Sir Kingsley Wood, on Saturday last issued a communication to local authorities and other water undertakers on the question of their water supplies. He feels it incumbent upon him, in the light of recent experience, to remind water undertakers of the serious responsibility that rests upon them in relation to the purity of the water supplies they control. He points out that it is the statutory duty of all local authorities operating under the Public Health Acts to ensure that water supplied by them to consumers is at all times wholesome, and a like responsibility is expressly placed by Parliament upon water undertakers, whether local authorities or statutory companies, who derive their powers from special statutory enactments.

Appointment of Water Engineers

The communication states that the relative immunity from serious outbreaks of water-borne disease that the country has long enjoyed must not be allowed to obscure the paramount importance of taking all possible steps to ensure that this responsibility is adequately discharged and every practicable precaution adopted to safeguard the purity of supplies. The machinery and methods of control, which must necessarily vary with the circumstances of different undertakings, are matters for the decision of the responsible authorities themselves, but it will be realized that the first necessity is that the undertaking should be under the supervision of a qualified engineer who, in the case of the larger undertakings owned by local authorities, should be a chief officer of the authority directly responsible to the appropriate committee, and in all cases should be in a position to give detailed personal attention to the work.

The Minister states that he has no doubt that water undertakers generally will appreciate the need for maintaining the high standards of administration rightly demanded in a matter of such fundamental importance to public health, but the results that may ensue from neglect of precautionary measures are so serious that the Minister regards it as his duty to impress upon all water undertakers the imperative need for unremitting care in the supervision of the water supplies for which they are responsible.

Constant Watch Necessary

Where water is being supplied without treatment the water undertakers must satisfy themselves that this practice can safely be continued. For this purpose they should keep a constant watch on the quality of the water by frequent analyses. How often the analyses should be made in a particular case depends on local conditions—for example, on the character of the source and of its gathering ground and their position in relation to each other. The Minister is satisfied that under modern conditions more frequent analyses are needed in many cases as a minimum precautionary measure, particularly where there is a tendency to fluctuation in the composition or bacterial content of the water. The water undertakers should be guided as to the frequency of analyses by the views of their expert advisers after examination of the local conditions. It is not sufficient, however, to rely on results from analyses alone. Regular and frequent inspections should be made of the area forming the gathering ground of any spring or stream used as a source of supply and of areas surrounding underground sources of supply situate in or near the outcrop of the strata from which the water is drawn, and all practicable steps should be taken to remove possible sources of contamination in these areas. If as a result of their analyses and

inspections or for any other reason the water undertakers have cause to think that any of their sources of water supply cannot be made and kept free from liability to pollution, they should immediately treat the water by effective methods of purification.

Control of Treatment of Water

Where the water is treated the treatment should as far as possible be automatically controlled, and where the treatment includes chlorination the dosage should be automatically and continuously recorded. The efficacy of any form of treatment given should be verified by frequent tests of the treated water. The method, extent, and control of treatment required in any particular case are also matters on which the water undertakers should be guided by expert advice. Periodic analyses should be made of the raw water in order to keep a check on any change in its character and on the treatment needed. The Minister stresses the point that treatment of the water should be regarded not as a complete security in itself but as complementary to the taking of all practicable steps to seek for and remove the causes of pollution of the raw water.

Special Precautions during Works

Sir Kingsley Wood emphasizes that the utmost vigilance is also required to ensure that no risk of contamination of the water supplies arises from operations in connexion with the normal maintenance and improvement of waterworks, such as extensions of the works, the re-conditioning of wells, reservoirs, and filters, the repair of pumping plant, etc.; and in some cases—for example, where men are engaged on work in a well—it is essential either to cut off the supply from the well until after the work is completed or to give precautionary treatment to the water.

Importance of Co-operation

The Minister further points out that the administrative responsibility for a service of such vital importance to health can only be successfully discharged if there is effective collaboration and co-operation between those responsible in their various capacities for the conduct and efficiency of the undertaking and between the water undertakers and the local authorities of areas served by them. It is essential that local authorities who are themselves water undertakers should ensure that the water committee and its officers work in close co-operation with the public health committee and the medical officer of health. Where the water undertakers are not the local authority for an area supplied by them they should always be ready, on request, to furnish full information to that local authority or its medical officer of health as to the quality of the water supplied and the precautions taken to safeguard its wholesomeness. On the other hand, local authorities should make it their duty to bring to the notice of water undertakers cases of enteric fever or other diseases likely to be water-borne, and also any building development or other operations in the local authority's area which might affect the purity of a source of water supply.

On March 8 the Croydon Borough Council authorized its special Typhoid Committee to appoint a water engineer as a principal officer of the Corporation, in accordance with the suggestion made in the report of the public inquiry by Mr. Harold Murphy, K.C., and endorsed in the letter sent to the Corporation by the Minister of Health. On March 14 the Council agreed to set up a committee to deal exclusively with water matters.

ENGLAND AND WALES

MARCH 19, 1938

Local News

ENGLAND AND WALES

Blood Sedimentation Rate Test

The Empire Rheumatism Council has convened a meeting of medical scientists to consider means to endeavour to standardize the blood sedimentation rate test, important in the treatment of rheumatic disease. The meeting will be held at the Royal Society of Medicine at 11 a.m., Saturday, March 26, the opening day of the International Congress on Rheumatism. The following have accepted invitations to attend: Dr. Douglas Collins, Harrogate; Dr. Harry Coke, London; Dr. Warren Crowe, London; Professor S. Davidson, Aberdeen; Dr. Gibson, Bath; the pathologist, Charterhouse Clinic for Rheumatism, London; the pathologist, St. John Clinic and Institute, London; Mr. Joseph Race, Buxton; Mr. H. B. Salt, Droitwich; Dr. J. W. Shackle, London; Dr. L'Estrange Orme, London; Dr. C. W. Buckley, Buxton; Sir William Wilcox, London; Dr. C. W. Gordon and Dr. W. S. C. Copeman, chairman and hon. secretary respectively of the Scientific Advisory Committee of the Empire Rheumatism Council.

Moorfields Eye Hospital Dinner

The annual dinner of the Royal London Ophthalmic Hospital took place on March 10 at the Langham Hotel. The toast of "The Hospital and School" was proposed by the chairman, Mr. A. C. Hudson, consulting surgeon. Mr. Theodore W. Luling, chairman of the hospital, and Mr. Charles Goulden, dean of the school, replied. The health of the guests was proposed by Mr. R. Affleck Greaves, and Major-General W. P. Macarthur, Director-General A.M.S., replied. Mr. P. G. Doyle proposed the health of the chairman. In responding to the health of the school the Dean incorporated his report. The entries, he said, were even larger than in 1936, and October, 1937. Seventy-seven old students had continued their attendance. British Postgraduate Medical School, these being in addition to the numbers given. The examination results had been satisfactory, and various honours had fallen to old students during the past year. The Dean again drew attention to the urgent need of ophthalmology being placed in its proper position in relation to the other branches of medicine by the foundation of a professorship and a suitable team of helpers. Until this was done it was impossible to achieve more in the direction of teaching and training.

Maternity Scheme for the West Riding

Some idea of the West Riding County Council's scheme for the provision of hundreds of maternity beds in the West Riding and of a medical services scheme was given at the opening of the new Listerdale Maternity Home, Rotherham, reported in the *Yorkshire Post* of March 14. Maternity homes and maternity units are to be provided throughout the West Riding at a capital cost of £308,000, with an annual maintenance cost of £45,000. The Listerdale Home is the first to be opened directly under the control of the county council, and is the forerunner of other schemes for the provision of a further 300 maternity beds in the West Riding. Councillor W. T. Blewitt announced the beginning of a scheme on April 1 to provide home help, and said they had already had hundreds of applications from young women prepared to do the work. Alderman Cartwright said it was proposed to put a unit of £80,000 and a maintenance cost

of £1,586 per year. At Skipton they were going to put a unit of eight beds. At Keighley there would be a new unit, and in the great new hospital in North-West Yorkshire there would be a maternity unit of fifty beds. At Staincliffe there would be fifty beds, and at Wakefield eighty beds. The new general hospital between Barnsley and Doncaster would provide another twenty beds.

Anti-gas Training at L.C.C. Hospitals

Many of the London County Council's hospitals and other institutions would, in the event of war, be used as casualty clearing hospitals and base hospitals, and it is considered essential that the whole of the staff at these establishments, except purely casual employees, should receive anti-gas training. Almost all the medical and senior nursing staff of the hospitals and mental institutions have already received training from Home Office instructors, and those so trained are undertaking that of the junior nursing staff. Other arrangements, however, have to be made for the training of the non-professional staff, numbering several thousands, many of whom will be required to perform duties in connexion with cleansing contaminated casualties, decontaminating buildings, and forming fire squads. It is accordingly proposed that five officers in the Council's service who have been trained as qualified instructors at the Government civilian anti-gas school, Falfield, shall be released from their ordinary duties so that they may undertake the training of the staff. It is expected that the work will be substantially completed within twelve months.

IRELAND

The Queen's University of Belfast

During the past few days an appeal has been sent to graduates of the Queen's University for subscriptions to a fund which has been inaugurated to meet the urgent needs of the University. It is pointed out that the income is just sufficient to "carry on" in a manner which does not do justice to the progressive spirit and enterprise of the Ulster. The need for modern laboratories is urgent, but even more clamant is the need for proper buildings to house the departments that are accommodated in the old wooden erections used for the U.V.F. Hospital during the war. The latter have been in use long past the usual span of life of wooden buildings, and their further repair and maintenance is rapidly becoming out of the question. And yet they are the only available place for housing the various departments of one of the most progressive universities in the Kingdom. A scheme for the orderly and harmonious development of the University which will meet the more urgent needs has been prepared by the architects, but for this a sum of upwards of £250,000 is required. The financial position has caused a great deal of anxiety to the University authorities as the income from all sources is considerably less than half of that of any other university of a similar size and age in the United Kingdom. The Vice-Chancellor produced the following figures of the number of students and the income of universities during 1935-6:

	Number of Full-time Students	Total Income
Belfast	1,567	£95,263
Birmingham	1,437	£217,904
Bristol	1,033	£200,143
Leeds	1,663	£264,954
Liverpool	2,119	£250,104

The appeal eloquently states: "That the academic results achieved here are out of all proportion to the

whatever in the excretion of sugar, and in a number of other cases, while there was an increase, it was not of such an order as would have followed an equivalent amount of protein in the ordinary form. Dr. R. D. LAWRENCE said that he had had some slight experience of the profarin preparation. It had no appreciable starch or soluble carbohydrate in the usual sense. He thought it desirable that further work should be done on adult cases not having insulin.

TOMOGRAPHY

At a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland on February 11 Dr. F. G. STEWART read a paper on tomography in chest radiography.

Dr. Stewart said that tomography was the taking of a radiograph of a section through the patient, objects in planes superficial or deep to this selected plane being blurred out; several tomograms were needed in each case. Films were shown illustrating the value of the method in demonstrating cavitation in pulmonary tuberculosis. In twenty-two out of fifty cases tomograms gave an altogether different conception of the underlying pathology; unsuspected cavitation was demonstrated in 40 per cent., and in 74 per cent. information additional to that obtained by ordinary radiography was given.

The president, Dr. E. T. FREEMAN, said that at the meeting of the Association of Physicians in Sheffield in 1934 a tomograph had been exhibited the cost of which was £1,200. The model designed by Dr. Stewart was considerably cheaper. In the discussion which followed many members took part, among them being the president of the Academy, Dr. A. R. PARSONS, and Drs. H. F. MOORE, T. M. CORBET, W. R. F. COLLIS, J. C. FLOOD, ST. G. SMITH, and A. THOMPSON. Several questions were asked, and Dr. STEWART, in replying, said that what he had done was just to alter slightly Twining's modification of the tomograph, which meant that it could be produced at a lower cost.

INDUSTRIAL DISEASES

At a meeting of the West London Medico-Chirurgical Society, held at the West London Hospital on March 4, with the president, Dr. D. G. RICE-OXLEY, in the chair, a lecture was given by Dr. DONALD HUNTER on industrial diseases.

Dr. Hunter began with a reference to the diseases of coal-miners, in particular miners' nystagmus and "beat knee," the latter caused by the cramped posture in which the men worked in the pit. In the iron-mining and smelting industries great precautions had to be taken for the protection of the eyes of the workers, and until this was done the toll taken of sight was enormous. More than once it had happened that an occupational disease or liability had been discovered, not by a medical man but by those engaged in the industry itself. For example, it was the secretary of the glassblowers' trade union who, at the end of last century, discovered the condition known as glassblowers' cataract. As a result of the precautions now taken this condition was disappearing. Turning to anthrax, the lecturer mentioned that at the London Hospital, over the period 1884 to 1935, the cases had numbered 116, of which ninety-eight were occupational. Of these only one was of the deadly pulmonary type, and among the whole of the cases the deaths had numbered only eleven. He described the precautions taken to prevent anthrax among wool-sorters by the careful cleansing of all wool at the port at which it was landed

in this country. The same methods of protection, however, were not applicable in the case of furs and skins. He next mentioned Weil's disease, to which London sewer workers were particularly liable. It was a disease of very wide occurrence, and was found in workers in the sugarcane fields of Queensland and on the canals of Holland. After touching upon some of the new diseases which were appearing with developments in chemical industry—such, for example, as the use of alkalis for chlorination processes—he mentioned the heavy toll of life which lead poisoning had exacted. Even now, owing to the carelessness of workers in some departments, lead poisoning was not infrequent. He objected in particular to the spraying of lead pigment by means of a gun, which he described as an invention of the devil. Occupational dermatitis in its many forms was mentioned, alkalis heading the list of causative agents. Chromium salts also caused a very severe dermatitis. In considering occupations which involved the risk of cancer the industrial use of x rays should not be overlooked. A large number of industrial workers were now using powerful x-ray apparatus, and it seemed possible that the same calamity might befall some of them as befell the early medical pioneers in this subject.

Means of Prevention

After referring to diseases caused by dust, and mentioning the most dangerous of dusts—namely, silica and the silicates—Dr. Hunter suggested the various means of preventing disease in industry. The first line of prevention was the elimination of dust and fumes. The next was the installation of protective apparatus uncontrolled by the workman; and the third, the education of the workman as to the nature of his dangers. Cleanliness of working places and the bodily cleanliness and general hygiene of the worker were obviously important. England protected the workman in its factories against disease better than any other country in the world, not excepting Germany, where the regulations were more stringent but were less punctiliously followed. England had also the advantage of a Factory Department of the Home Office, which was at all times ready to give advice and to take any necessary action.

At a meeting of the Devon and Exeter Medico-Chirurgical Society on February 24, with the president, Dr. ROBERT SCOTT, in the chair, Dr. FRANK ROPER showed a case of what he termed emphysema of unknown origin, the treatment of which was discussed by Dr. R. L. MIDDLEY. Dr. MARSHALL SCOTT showed a decidual cast from the non-pregnant horn of a bicornuate uterus. A thirty-seven weeks' foetus was delivered from the right horn and the cast was expelled from the left horn on the fifth day of the puerperium.

O. Henrich (*Zbl. Chir.*, February 5, 1938, p. 316) reports a case of benign ulceration of the rectum. He believes that the condition is much more frequent than is generally assumed, though the diagnosis is often missed. The lesion is usually mistaken for an inoperable carcinoma of the rectum; the patients, however, are cured after some time. In the case reported by the author the condition proved inoperable, and a colostomy was performed. After ten weeks all traces of the tumour disappeared and a retrospective diagnosis of benign ulceration with an extensive inflammatory infiltration was therefore made. Laparotomy one and a half years later confirmed the absence of neoplastic infiltration. The rectum, however, was stenosed and the colostomy had to be left open.

SCOTLAND

psychiatric field, and this was likely to perpetuate the schism between the physical and the mental which medical men had been endeavouring to bridge. Medicine needed the help of every intelligent person interested in the problems of human betterment, but it was the physician alone who realized the complexities of treatment for highly charged emotional disorders. Civilized people could not be divided arbitrarily into the sane and the insane, nor between these groups there were a large number who were unable to adapt themselves to ordinary social life. Prison methods had little to offer in this respect, and, moreover, such cases did not fit in with the regime of a mental hospital. The disorder or conduct had been present from early childhood, and it was of altruistic feeling, moral blindness, or selflessness. These cases were very important for three reasons: first, because they were very numerous; secondly, because they were the most disruptive element in society; and, thirdly, because there was no adequate provision for them. The problem of treating them was far too big for private practice, and was closely bound up with public health, social welfare, and education throughout the country. It was necessary for their treatment that a more positive health policy and more positive health laws, of which education was a fundamental part, should be developed rather than lunacy laws.

SOME PROBLEMS IN GLASGOW

Professor J. W. McNece, presiding at the annual meeting of the Royal Mental Hospital, Glasgow, on February 25, said that this hospital, originally founded as a charitable institution, had undergone great changes to meet altering circumstances, and was now essentially a pay-bed hospital. Its income being derived partly from accumulated funds but mainly from the fees paid by patients was devoted and maintenance. All the income, however, was devoted to the hospital itself, and it was governed by a voluntary body of citizens of goodwill. Psychological medicine was merely a specialized branch of general medicine. Students in Glasgow were adequately trained to deal with psychoses, but in general practice psychological disturbances not amounting to certifiable insanity were far commoner than frank psychoses and bulked more and more in ordinary practice. Of necessity the mental hospital was almost entirely filled with cases of real psychoses, and therefore provision must be made for teaching students, which they would have to carry out mainly themselves. For this reason a clinic was held once a week at the Western Infirmary. The speaker believed that many of the patients seen at this clinic should be admitted for treatment, and they would go willingly into wards attached to an ordinary general hospital. The report of Dr. Macniven, physician-superintendent, emphasizes the difficulty that during the past year there was considerable difficulty in maintaining an adequate staff of female nurses in the hospital, particularly because of the necessity for increasing the staff in order to introduce shorter working hours. It was found that since 1913 from one-quarter to one-half of the nurses who entered the service failed to complete their three years' training, and this did not make for efficiency. The fact that the mental nurse was regarded as holding a lower status in the profession than the general trained nurse was one reason why mental nursing was not more popular. The remedy appeared to be to introduce a comprehensive training for all nurses which would include mental nursing as part of a mental hospital would give the general trained nurse a better orientation in her work. The necessity for a pension scheme applicable to all classes of nurses was obvious, and the absence of an interchangeable pension scheme in royal mental hospitals placed these in an unfavourable position for recruitment of nurses.

Vital Statistics of Scotland

The supplementary return of the Registrar-General of Scotland for the year 1937 is included with the quarterly return for the last quarter of that year. The return shows that the birth rate for the year of 17.6 per 1,000 was with one exception the lowest yet recorded for Scotland. The death rate was 13.9 per 1,000, being 0.5 higher than in the previous year. Maternal mortality showed a marked decline, being only 4.8 per 1,000 live births as against 5.6 in 1936. The total number of births during the year was 87,812, and the deaths from all causes 68,942. Deaths of children under 1 year numbered 7,050, giving an infantile mortality rate of 80.3 per 1,000, or 2.0 below that for the previous year. There were 2,693 deaths from influenza, this being the highest recorded for any year since 1929, when there were 3,435 deaths from this cause. All forms of tuberculosis accounted for 3,663 deaths, the rate being 4 per 100,000; the rate for the respiratory form of the disease was 56, or 1 more than in the previous year. For the first time in the last ten years the deaths from malignant disease were fewer than in the preceding year, the number being 7,811 as against 7,909, and the death rate 157 per 100,000. The number of deaths certified as due to heart disease continued to increase—14,358 as compared with 13,698 in 1936; the recent increases were attributed to more definite specification of the cause of death.

Aberdeen University

Aberdeen University Court, at a meeting on March 8, accepted the resignation of Professor Alexander Low from the chair of anatomy on September 30 next. Professor Low graduated M.A. at Aberdeen in 1891, and M.B., C.M., in 1894, taking the M.D. in 1912. He became an assistant in the anatomy department at Aberdeen immediately after qualifying, and was later appointed reader in embryology. He succeeded Professor R. W. Reid in the chair of anatomy in 1925.

Dr. James William Howie, M.B., Ch.B., was appointed the first lecturer in bacteriology in the university. He has been assistant in bacteriology in Glasgow University and assistant pathologist to the Western Infirmary.

At the same meeting intimation was made of a gift to the university from Sir Ian Forbes Leith of Fyvie Castle, consisting of the library of Professor John Gregory, who was professor of medicine at Aberdeen, and later at Edinburgh, about the middle of the eighteenth century. The library includes over 2,000 volumes.

FRANCE

[FROM OUR CORRESPONDENT IN PARIS]

Significant Trends in French Medicine

This year's president of the French Academy of Medicine, Professor F. Bezançon, devoted the greater part of his opening presidential address to a discussion of the most significant trends in French medicine to-day. He joined issue with those foreigners who see in French medicine a slave-like attachment to clinical teaching based on the traditions of the great masters of the past to the exclusion of a sufficient share of technical science. This estimate, in Professor Bezançon's opinion, does French medicine injustice. Clinical research, he said in effect, is, at its best, science of a very high order, and has yielded epoch-making discoveries which the laboratory may confirm but did not originate. The modern science of endocrinology, for example, is entirely derived from clinical observation. As for the future, it undoubtedly belongs to clinical specialization allied to scientific methods. "We must seek more and more to be men of science, well grounded in science and, above all, trying to acquire the scientific

meagreness of our resources is familiar to everyone acquainted with universities; but equally it is obvious that no amount of enthusiasm or ingenuity can overcome the very grave handicap from which Queen's students suffer in the lack of provision for teaching, equipment, and research." It is pointed out that in almost all departments there is a paucity of lecturers and other junior staff which severely limits the teaching and the extent of individual attention available to students; several principal subjects either lack a professorship or are unrepresented altogether. It is to be hoped that the aims of the Appeal Committee will be reached, and that a generous response from all old Queen's men will be forthcoming to meet a call which should find a ready response from those who owe their present position to their alma mater.

Ulster Medical Society

One of the most successful sessions of the Ulster Medical Society, over which Professor W. W. D. Thomson has presided, is drawing to a close. The president's opening address on "Some Aspects of the Life and Times of Sir Hans Sloane," to which reference was made in these columns on February 12 (p. 349), was a masterly presentation of a subject which has not hitherto attracted the attention it deserved. An outstanding meeting of the session was the Robert Campbell Memorial Oration delivered by Dr. Leonard Colebrook, who took for his subject "The Control of Infections due to Haemolytic Streptococci." Dr. Colebrook gave an appreciative audience an account of the present position in this important field of medical interest and research, and his paper was published as a supplement in the *Ulster Medical Journal* (1938, 7, 1). At the conclusion of the meeting Sir Thomas Houston presented the orator with the Robert Campbell Medal. Other papers contributed were of general and special interest and prove that the Society is very much alive to its responsibilities. On February 24 Dr. William Moodie of the London Child Guidance Clinic discussed the working of a child guidance clinic, and on March 3 the penultimate meeting of the session was held in the Institute of Pathology, when the members were the guests of Professor Biggart and his staff to inspect a display of clinico-pathological and pathological material. The manner in which the specimens were set out, with full clinical records and reports, was much appreciated, and the interest shown by the members was a measure of the praise due to the organizers of the meeting. During the past year the Society has lost two of its Honorary Fellows in the persons of Sir Thomas Moore of Dublin and Professor W. St. C. Symmers. Among the names added to the list this year are those of Sir Humphry Rolleston and Sir Robert Johnstone.

Royal Victoria Hospital: Musgrave Clinic

The new paying patients pavilion of the Royal Victoria Hospital, Belfast, which has been opened by the Lord Chief Justice of Northern Ireland, the Right Hon. James Andrews, K.C., owes its existence to a generous benefaction of the late Henry Musgrave, who left the residue of his estate for some necessary extension of the hospital. The trustees felt that a clinic for paying patients of moderate means would meet in every respect the wishes of one who had always given very generously to charitable objects in and around Belfast. The clinic has accommodation for 52 patients (44 single-bed wards and 2 four-bed wards). The operating theatres are lavishly equipped and spacious in size; there is a modern x-ray installation and equipment for electrotherapy. Suitable waiting and rest rooms for relatives are provided, and the kitchen appointments leave nothing to be desired. That the clinic will provide a long-felt want and prove popular is shown by the rapid filling up of the rooms; already it is working almost to capacity. Altogether the Royal Victoria Hospital, the Royal Maternity Hospital, and the Musgrave Clinic have about 700 beds, and the fact that they are grouped together in the same grounds as the new Nurses'

Homes and the Queen's University Institute of Pathology, forming a colony of medical and surgical treatment and research second to none in its quality and usefulness, adds to the sense of pride of those who conceived and carried to fruition such an ambitious project.

Medical Research Council of Saorstát Éireann

The Medical Research Council of Saorstát Éireann (whose offices are at 85, Merrion Square, Dublin) has made the following awards: Dr. R. A. Q. O'Meara, whole-time appointment for one year to investigate the experimental production of therapeutic antisera, the work to be carried out in the School of Pathology, Trinity College, Dublin, under the direction of Professor J. W. Bigger. Dr. J. C. Flood, part-time appointment for one year to carry out an investigation of the total body electrolyte, work to be done in the Pharmacological Laboratory, University College, Dublin, under the direction of Professor E. J. Conway. Professor J. H. Biggart, grant-in-aid to purchase special apparatus in connexion with a series of researches to be carried out in the Institute of Pathology, Queen's University, Belfast. Dr. P. C. Bresnahan, grant-in-aid to cover laboratory expenses in connexion with his training in the Pathological Institute, Freiburg, under the direction of Professor Buchner. Miss M. O'Sheehan, grant-in-aid for expenses in connexion with an investigation regarding the isolation and chemical identification of a substance in urine related to vitamin C, the work to be carried out in the Department of Pathology, University College, Cork, under the direction of Professor J. Reilly. Dr. J. D. H. Widdess, grant-in-aid to enable him to receive a short period of training from Professor J. H. Biggart, Institute of Pathology, Queen's University, Belfast, in connexion with an investigation of the pathogenesis of diabetes insipidus.

SCOTLAND

Treatment of Mental Disorder

At the annual meeting on February 28 of the Royal Edinburgh Hospital for Mental and Nervous Disorders Professor D. K. Henderson, physician-superintendent of the institution, presented his annual report, in which he discussed mental health policy. He said that the managers of the Royal Infirmary, Edinburgh, had co-operated in providing facilities for a psychiatric clinic and a child guidance clinic in their medical out-patient department. The essential aim of the child guidance clinic was to provide help for those children who found it difficult to adjust themselves to the home, the school, or social life in general. The majority of such children reached a high intellectual standard, and the problem they presented was quite different from that of the subnormal or retarded child. With regard to a mental health policy, the attention of the public should be directed to the broader issues of psychiatric work. The method of approach to mental illness was now to correlate the symptoms with the whole life-history of the patient and all the forces which had played a part in moulding his personality. Naturally, the earlier a patient placed himself under treatment and the more understanding he was the better would be the results. - One great difficulty was that nervous people disliked admitting that they were ill, and regarded themselves as failures and incompetents. It was important that the patient should realize there was nothing to be ashamed of and no reason why he should not be able to resume ordinary life. Physical and mental health could not be separated, for one was dependent on the other, and a recognition of this was now leading to much closer work between physicians and psychiatrists. In recent years the clergy and other lay persons who might have excellent academic qualifications were tending to invade the

detect, will be handed on by a raved individual to his offspring, and will form part of the general gene pool of mankind. Most of them, according to our experience of other organisms, may be expected to be deleterious. Many will be "lethals," whose effect is to cause early, often intra-uterine, death; but these are perhaps not so dangerous as the even larger class whose only effect is a slight lowering of viability.¹

There are two further points which are of importance. First, the effects of successive doses of x-rays are cumulative: two doses of one unit have the same effect on mutation as one dose of two units. Secondly, mutation may occur in cells at any stage of development and not only in mature gametes, so that after a period of temporary sterilization the newly formed gametes are liable to be affected, though it is probable that those with the strongest lethal effects are at least partially eliminated by cellular selection.⁴

The frequency of occurrence of individuals showing a deleterious condition determined by a rare recessive gene is simply related to the mutation rate of the gene in the population and the effective fertility of the affected individuals; if the condition is due to an autosomal recessive and leads to death before breeding, the frequency of occurrence is half the mutation rate per life cycle. Thus any increase in mutation rate will eventually lead to an increased incidence of the pathological condition in the population. It is, however, the mutation rate within the whole population with which we are concerned, and from the point of view of human biology the important thing is not the x-ray dose given to single individuals but the total quantity of radiation applied to the whole population. A single individual part of the germinal store of the next generation, and a doubling of the mutation rate within this fraction may legitimately be considered of minor importance. If x-ray treatment were applied to the greater part of the population the situation would be quite different, and a serious deterioration of the human material might be expected.—I am, etc.,

C. H. WADDINGTON
Strangeways Research Laboratory,
Cambridge, March 7.

After-effects of Modern Treatment of Carcinoma

SIR,—I feel inclined to agree with Mr. James Phillips (*Journal*, March 5, p. 538).

A few years ago I attended a patient who was suffering from bilateral endotheliomata of the inguinal lymph nodes. He was in hospital on several occasions. No operative removal was attempted beyond what was necessary for pathological examination. At intervals when he was allowed home he felt well, apart from inguinal discomfort and pains on lying down. During his last stay in hospital he received x-ray therapy. The growths started to slough shortly after he returned home; within three weeks all that remained were foul craters, as if some selective corrosive had been applied. Severe loss of flesh coincided with the destruction of the growths. It is unnecessary to say that he partook of his normal foods.

What struck me most in this case was the local malignancy but complete absence of metastases. The sloughing affected the growths very uniformly and left the surrounding tissues, even the blood vessels, severely alone. The loss of flesh after x-ray therapy may have been caused in several ways: (a) by absorption of toxic products

from destruction of the growths; (b) by secondary infection (this patient was apyrexial during the whole period and even the surrounding tissues appeared to be free from secondary inflammation); (c) it may have been a coincidence; and (d) the x-ray therapy, as suggested by Mr. James Phillips, may have been at fault. I think this last is the most probable.—I am, etc.,

E. S. LEE.
Dalmellington, Ayrshire, March 7.

SIR—I think Mr. James Phillips's dismay at the lamentable results of x-ray treatment of malignant tumours (*Journal* March 5, p. 538) is not unusual, although not so painful as in Mr. Percy Furnivall's case (*February 26, p. 450*). My personal experience may be of interest.

I am 77 years of age, weigh 10 to 11 st., of which I have lost a stone, and have always had good health. Even now my general condition is good; I can read, smoke, and sleep well when allowed. In January, 1936, cancer of the rectum was diagnosed, the growth being about the size of a guinea-fowl's egg. I went to London and, owing to my antipathy to x-rays, I was put under deep x-ray therapy for three months. I had thirty applications, which did not cause much inconvenience. At the end of this time the size of the growth had been reduced by half. I was at home for a fortnight, then went up again, but took the precaution of being cystoscoped before I underwent the radium treatment. The urethra was found healthy, and the prostate slightly enlarged.

On May 11, 1936, I had radon seeds in the rectum for twenty-five hours in two nights. The radon seeds being in an inflated rubber bag. I was sent home and warned that the reaction would take place in a fortnight. It did. On May 23 a profuse purulent reaction began and still persists, with a stricture was practised. In July signs of obstruction appeared, and early discharge. In September I was digitally examined and only found half-way up the rectum. On September 22 I had a colostomy performed. The growth had disappeared and only a fibrous band was left. I went home, and had a nurse who washed me out on alternate days. I was able to get up for lunch, rested, and then retired at 6.30 p.m. This went on until August 31, 1937, when there was a serous discharge from the colostomy opening of the upper part of the rectum, which did not appear to have been involved previously. At the same time a perforation took place between the rectum and bladder, which had been painful, with difficult micturition, for some time. Almost all the urine is passed per rectum, and since I have been bedridden the serous discharge has persisted until early March, when I presume, the hour-glass stricture relaxed and allowed the discharge to percolate into the lower chamber; now the rectal sphincter has started leaking, which makes the dressings wet.

The sum of it all is that the treatment with radium has arrested the growth, but has so damaged the pelvic viscera that there is little hope of tolerable comfort for my few remaining years.—I am, etc.,

WILLIAM GOSSE, M.D.
Wimborne, March 12.

SIR,—I fear the account of Mr. Percy Furnivall's unfortunate experience after treatment by radiotherapy (*February 26, p. 450*) will give an unbalanced impression of modern results, unless in all fairness more evidence in a contrary sense can be stated. I therefore ask your leave to give a brief account of an elderly private patient, with a lesion apparently similar, who has given me a personal description of the after-effects of deep x-ray therapy in her own case.

The patient, a lady now aged 85 years, was seen originally by me in August, 1936, and gave a history of six months' duration. The diagnosis of epithelioma of the tonsil was confirmed by biopsy. I referred her for treatment to Dr. Gwen Hilton, radiotherapist to University College Hospital. She attended the hospital daily from a hotel near by. The general disturbance of hotel life as compared with home life,

¹ N. W. Timofeev-Ressovsky, *Nachr. Ges. Wiss. Gött.*, 1935, N.F., Bd. 1.
⁴ *Biol. Zentralbl.*, 1937, Bd. 57.

spirit, but we must continue first of all to retain a thorough clinical education, and let us remember that this is not to be found in laboratories and lecture halls but in the hospital and in practice out in the world. . . . With us bedside observation and intern service in hospital are at the root of French medicine."

Conseil Supérieur d'Hygiène Sociale

M. Rucart, the Minister of Public Health, issued early this year a decree which embodies in a single central council all the commissions, associations, etc., which have hitherto concerned themselves with various aspects of social health and welfare. Among the organizations labelled as "suppressed" by a stroke of M. Rucart's pen are such important bodies as the Cancer Commission, the Permanent Rheumatism Commission, and the Tuberculosis Commission. The new central body is to consist of seven commissions, the first three of which will be exclusively concerned with tuberculosis, venereal disease, and cancer respectively. The importance attached to rheumatism as a social problem is indicated by the creation of a commission devoted solely to this subject. Another commission will be concerned with the problems of nurses and social service workers. Documentation and propaganda share a commission between them, and there is to be one for health and social co-ordination and the maintenance of contacts with the national insurance services. If it is not too unwieldy this new central body ought to be able to act with more administrative efficiency than the individual organizations it has replaced.

Professor Leroux's New Appointment

When Professor Roussy accepted the appointment of Rector of the Academy of Paris he resigned his professorship of pathological anatomy. The vacancy thus created has been filled by Professor Leroux, who has served under Professor Roussy since 1919 in various capacities. Since 1926 he has been subdirector of the Cancer Institute, with which Professor Roussy has been so closely associated. Professor Leroux's most recent work in the field of pathological anatomy has been concerned with malignant disease.

Control of Sera and Vaccines by the Academy of Medicine

The supervision of the production of sera and vaccines by a special commission of the Academy of Medicine has hitherto provided a valuable check on manufacturers tempted to err from the narrow path of commercial rectitude. But this supervision has naturally entailed the employment and payment of a highly technical staff, and when the Academy recently made application for funds to increase this staff the Government, represented by the Minister of Finance, refused the wherewithal. The Academy's response to this ill-advised economy is a note addressed to the Minister of Public Health, in which it states that it will henceforth be unable to examine any new preparation submitted to it.

Professor René Leriche at the Collège de France

The appointment of René Leriche of Strasbourg to the professorship at the Collège de France in succession to Charles Nicolle is a most popular one, and when the new-comer was to give his opening address in Paris the other day a large part of his would-be audience formed a queue reaching well out into the street. It is, of course, difficult to decide how much the remarkable hold Leriche has on the medical world to-day depends on his personality and how much on the solid gains he has achieved in the surgery of pain and of the endocrine glands. His operations on the sympathetic nervous system would alone qualify him for a high place in the

history of medicine, and it may be truthfully said of him that while his hands are the hands of a surgeon, his brain is that of a physician thinking in terms of physiology. The Collège de France, with which he will henceforth be associated, was founded in 1530 by François I. The first reader in medicine was a Florentine, Vadius Vidi, who was invited by François I to Paris. His successor was Jacques Sylvius of Amiens. During the French Revolution the Collège de France was the only teaching institution allowed to continue its activities, although several of its professors were imprisoned. More recently the Collège was honoured by its association with such names as Laënnec, Magendie, Claude Bernard, Brown-Séquard, and d'Arsonval, the latter now living in remarkably active retirement.

Correspondence

Effect of X Rays on Hereditary Mutation

SIR,—In the *British Medical Journal* of February 19 Dr. Louisa Martindale, after alluding to the discussion of the Sections of Radiology and of Obstetrics of the Royal Society of Medicine reported in your number of January 29, put forward the suggestion that x-ray treatment might provide a convenient method of temporary sterilization which could with advantage be used as a technique of contraception. She made no reference to the effect of x rays on hereditary mutation, and this aspect of the matter was not touched on in the meeting referred to. Dr. M. Donaldson, indeed, did suggest the need for caution in applying x rays to germinal tissue until it is quite certain that this leads to no harmful results in the offspring. The danger, however, is more insidious. We know that a dose of 30 r units doubles the mutation rate in *Drosophila*,¹ and the effect in mice seems to be of the same order of magnitude.² The effect in man³ may perhaps be somewhat lower, since the spontaneous mutation rate of the haemophilia gene, which is the only human one for which we have any data, is about 100 times less, in terms of the number of mutations per year, than is usual in *Drosophila*.⁴ But we do not yet know how closely the rate of x-ray-induced mutation is correlated with the spontaneous mutation rate, and it is unsafe to assume that x rays have 100 times less effect on man. Even if this were so the effect of the commonly used doses would not be negligible on the mutation rate in the individual concerned.

Most of the mutated genes are likely to be recessive, so that they will not be manifested until two individuals each containing the same mutated gene come together in mating. The immediate offspring of a fayed individual are therefore very unlikely to show the harmful hereditary factors which they contain. Indeed, in an organism like man it will probably always be impossible to measure the change in mutation frequency caused by x rays with the accuracy which can be obtained by special breeding methods in *Drosophila*. But the mutated genes, however difficult to

Undulant Fever in Malta

SIR.—Dr. J. E. H. Gatt's article on undulant fever in Malta (*Journal*, February 26, p. 454) contains certain statements which cannot be allowed to pass unchallenged. In the first place, the average duration of the infection is nearer three months than six, according to an analysis made by Hughes and myself of 1,000 consecutive cases from the records of the Central Civil Hospital. As a rule there is a marked leucopenia and not a leucocytosis, and in fact this is a diagnostic feature. The mononuclears are not affected in any way, but there is a slight relative mononucleosis and a more pronounced relative lymphocytosis, since the reduction in the number of leucocytes is mainly at the expense of the polymorphonuclear cells. Perhaps Dr. Gatt uses "mononuclears" as synonymous with lymphocytes when he refers to the frequency of 50 per cent. Dr. Gatt also mentions the frequency of tubercle as a secondary infection; this belief is widely prevalent in Malta, but it has no scientific foundation. The previous incidence of undulant fever in one hundred cases of pulmonary tuberculosis was no higher than in another one hundred unselected cases, and although I am particularly interested in both diseases I cannot recall a single instance in which the development of tuberculosis was influenced by undulant fever. The myth arose from the close similarity between the two infections. A tubercle temperature with no physical signs in the chest is often diagnosed as "clinically undulant fever" until the signs appear, when it becomes "post-undulant tuberculosis."

With regard to treatment, vaccines in the ordinary sense—that is, particulate bacterial vaccines—have been repeatedly proved to be not only ineffective but positively harmful. There was a time when a filtrate—melitin or brucellin—appeared to have an almost specific effect, but extended experience with this method of treatment has shaken my faith in its efficiency. We know so little about the immunology of undulant fever that our crude attempts at specific therapy may do more harm than good. The intradermal injection of melitin and of *Br. abortus* emulsions in goats as a diagnostic measure has been tried at the Brucella Research Station in Malta, but the method has been found to be unreliable, inconvenient, and inferior to the agglutination reaction carried out by Huddleson's rapid method.

It is difficult to understand the possible use of "the preventive vaccine with live, non-virulent organisms . . . for infected animals" to which Dr. Gatt refers. If the animals are already infected, what is the use of prevention? The use of a live vaccine as a prophylactic measure is open to many objections, which cannot be discussed here, but I believe that the Ministry of Agriculture in England is opposed to its employment. In Malta a large-scale experiment is being carried out on the possibility of immunizing goats by the injection of a filtrate of avirulent bacteria. The results should be available in from six to nine months, and whether the method proves to be successful or not much valuable information will have been obtained on the immunology of this most interesting but most elusive of infections. The slight misstatements which I have attempted to correct do not detract from the value of Dr. Gatt's paper; but it is important to draw attention to them now, as otherwise they might be copied and recopied and in time would acquire vested rights.—I am, etc.,

J. E. DEBONO,
Member of the Undulant Fever Research
Committee.

Malta, March 1.

A. H. DOUTHWAITE.

London, W.1, March 12.

MARCH 19, 1938

benefit from mobilization and after-treatment as described by Dr. Douthwaite.

4. If the pain and limitation of movement of the shoulder-joint is due to bursitis, mobilization will be ineffective and the conditions require other treatment.

Finally, if during mobilization the "exudation" occurs by Dr. Douthwaite's technique, the results will be poor. But if on beginning mobilization the "tearing of wet wash-leather" feeling is experienced, further stretching of the joint capsule should be done, subsequent mobilizations being necessary, otherwise the "exudation" will occur, with inflammatory reaction likely to set in, and so retard rather than hasten the patient's recovery," as pointed out by Dr. Thomson.

C. B. HUGHES

London, W.1, March 13.

SIR.—Dr. F. G. Thomson in his letter to the *Journal* on several points of criticism of my recent article on this subject. His mention of fracture of the humerus resulting from manipulation is as irrelevant as if I had condemned diathermy on the grounds that it might cause a burn. In both cases the fault would lie with the operator and not with the method. Dr. Thomson writes that the tearing of adhesions results in the exudation of serum or blood with inflammatory reaction likely to set up more fibrosis and so retard the patient's ultimate recovery. The fact, however, remains that in every one of my cases restoration of movement has been recorded, maintained, and complete recovery has been obtained by the patients' doctors in thirty-five out of thirty-seven cases.

Dr. Thomson takes exception to my statement that the treatment of this condition by x-rays, baths, and dieting is futile and a waste of time, and declares that the cases respond quite well to balneological treatment, including manipulation in a pool bath. Dr. Thomson is either writing of a condition quite different from that which I described, or his happy experiences must be limited to the early stages of the disease, which should be treated, as I have already written, by rest, heat, and later by massage.

To suggest that the diffuse periarticular fibrosis with adhesions requiring considerable force for their rupture (I am using Dr. Thomson's description) can be cured by balneology can only indicate a failure to visualize the actual state which these words describe. It is true that with baths, heat, massage, and gentle manipulation a temporary improvement can be obtained, presumably as the result of stretching adhesions, but within a few weeks of return from Bath or other spa the condition is as bad as ever. When I tell Dr. Thomson that eighteen of my patients had been treated by the very methods he advocates, twelve of these having been at Bath, he will appreciate my reasons for scepticism in relation to balneological treatment of scapulo-humeral periarthritis as opposed to simple fibrositis of the shoulder girdle, with which perhaps he has confused it.

Mr. St. J. D. Buxton (*March 12, p. 589*) quite rightly assumes that I had no intention of giving a detailed description of the necessary manipulative technique. In point of fact, the essential thing to remember is that the shoulder-joint should be put through all its normal movements, though not necessarily at one sitting. I have not experienced difficulty in fixing the scapula hitherto, but shall certainly bear in mind Mr. Buxton's suggestions.—I am, etc.,

London, W.1, March 12.

together with the fatigue of fifty visits, was her chief trouble during the treatment. The pain in her throat before treatment was noteworthy, but it diminished after the first week. Her main complaint was dryness of the mouth, which persisted for over a year but is now considerably less. Her weight at the beginning of treatment on August 31 was 11 st. 1 lb., and at the end, in spite of an attack of influenza, had only fallen to 10 st. 9 lb. She has now returned to her original weight, and there is nothing abnormal to be found in her throat save some glazing of the mucosa of the pharynx. The skin of her neck is supple and free from any telangiectasis.

She tells me that she had no pain during the course of the treatment or afterwards, and that her eating and drinking were never seriously interfered with. After she recovered from the influenza her general condition improved rapidly, and she has been active beyond her years, even nursing her family. She is most explicit in her statement that the treatment was worth while.

The difference in response in these two cases has probably some technical explanation, but the point I wish to make is that the distressing symptoms which Mr. Furnivall has suffered are not a necessary sequence of the modern treatment of pharyngeal carcinoma by radiotherapy.—I am, etc.,

London, W.1, March 12.

D. J. COLLIER.

SIR,—Dr. J. H. Douglas Webster (March 12, p. 588) appears to think that I have been making an attack on ray therapy. My letter was an appeal for information as to whether any experimental work had been done on the effects of radiation on normal tissues. As Mr. Percy Furnivall states, there is much uneasiness regarding the far from infrequent disastrous after-effects on general well-being of ray treatment—either by x rays or by radium. Dr. Webster admits having such cases after the use of radium needles, and therefore he now suggests treatment by repeated doses of beam radiation.

I venture to inquire whether it would not be wiser to try to discover by experiments on animals the least harmful method of applying x rays, rather than trusting to arrive at a decision by the trial-and-error method on human beings. Won't one of the cancer research departments take this inquiry up?—I am, etc.,

Bradford, March 12.

JAMES PHILLIPS.

Co-operation

SIR,—The tone of the discussion in your columns on the securing of co-operation between a medical officer of health and the general practitioners in his area suggests that your readers might be interested to learn of the working of a co-ordinating committee, on the lines suggested, in a small borough.

The Accrington committee came into being as an *ad hoc* body, to discuss with the M.O.H. a matter of procedure, in November, 1936. After the amicable settlement of the point at issue the committee remained as a standing co-ordinating body, which did not propose to hold regular meetings, but which was available whenever either party desired to approach the other regarding matters of common interest. It has recently been of the utmost value in aiding the preparation of a diphtheria immunization scheme, and I am convinced that, while the occasions for its use are unlikely to be many or frequent, its existence is none the less of very considerable value. It is not to be expected that a medical officer of health and the private practitioners of his area will invariably agree, but even if the M.O.H. and the committee, in the classical phrase, merely "agree to differ," the fact that the matter has been discussed in this fashion

will produce a happier disagreement than might otherwise have occurred. Moreover, the feeling of confidence engendered by the committee's existence will probably render both parties less liable to magnify a trivial difference into a major grievance.

The value of the committee in times of epidemics will be comparatively small. Action and communication must be prompt, decisive, and direct; and the use of an intermediary for communication would give rise to undesirable delay. So far, at least, as administrative epidemiology is concerned, when epidemic disease is present the M.O.H. must necessarily be autocratic, but, of course, his "declaration of martial law" will be more effective and more easily acquiesced in if relations in time of epidemiological peace are on a democratic basis.

It should be sufficient for the committee to be recognized by the general practitioners themselves and by the M.O.H. without the formal recognition of the town council being sought. The latter might, in fact, prove a disadvantage, since the M.O.H. is the official adviser of the local authority in health matters, and that authority cannot well acknowledge the guidance of any other person or body. Official recognition of the committee might, quite possibly, lead to the ventilation of the committee's disagreements in open council, with the consequent risk of destroying any harmony previously established.

A further attempt at the securing of co-operation has recently been made in this area by the issue of a monthly bulletin to all general practitioners in the area. This bulletin gives an abstract of the borough's vital statistics for the previous month, together with such matters as the number of cases of certain non-notifiable diseases reported from schools and any other figures of interest. In addition it contains notes on any points to which I wish to call the attention of the practitioners (unusual clinical types of infectious disease; modifications in the local health services, etc.), and a brief extract of any Ministerial circulars or other topical publications which may be of interest. While it is possible to be sceptical about the practical value of such a publication, there is every reason to believe that in this area the bulletin is being generally appreciated. At any rate, it removes the reproach, too often heard, that the Public Health Department keeps itself to itself.—I am, etc.,

Accrington, March 7.

JOHN D. KERSHAW,
Medical Officer of Health.

Scapulo-humeral Periarthritis

SIR,—Dr. F. G. Thomson (*Journal*, March 12, p. 589) advances powerful reasons why mobilization of the shoulders without careful selection in cases of scapulo-humeral periarthritis may make the pain and limitation of movement worse. On the other hand, Dr. A. H. Douthwaite's technique and after-treatment for stiff and painful shoulder-joints (February 26, p. 441) yields in his hands a high percentage of successful results. There is nothing more difficult to decide than the type of case in which and the moment at which mobilization should be recommended and carried out. I have endeavoured to provide myself with certain guiding rules.

1. If pressure at, or near, the roots of the brachial plexus radiates pain into the shoulder-joint then the shoulder is not ready for mobilization.
2. If when the arm is abducted, the scapula being fixed as far as possible, pain is felt in the axilla and spreads over the shoulder, this shoulder also is not ready for mobilization.
3. If, however, pain is felt at one place only, and tends merely to increase at this place, then the shoulder will

relief and the patient complained of increasing pain and discomfort in the right iliac fossa. When examined, a tumour was discovered in the caecal region, and an x-ray film showed a filling defect of the caput caeci. At operation, however, the tumour was located not at the caput but on the inner side of the caecum and seemed to be continuous with a mass of glands which spread up along the ileo-caecal artery. There was considerable inflammatory reaction all around the caecum and the ileo-caecal junction. As the patient was frail and poorly nourished it was decided to do the operation in two stages. The ileum was anastomosed to the transverse colon, and two glands were removed for biopsy. Examination of the glands showed no evidence of carcinoma or tuberculosis but only chronic inflammation (Dr. W. W. Woods, London Hospital). There was no further operation. The tumour disappeared and the patient has remained well.

—I am, etc.,

London, W.1, March 15.

MICHAEL J. SMYTH.

Excision of the Patella

SIR,—The number of letters I have received since the publication of my recent article (*Journal*, February 19, p. 383) on the treatment of arthritis of the knee and fractures of the patella by removal of the patella prove the great interest taken in this operation. Professor Fawcett of Bristol informs me that a friend of his, the late Dr. Altham of Penrith, some forty years ago excised both patellae from a medical colleague for comminuted fractures which had become infected, and the patient stated afterwards that he was better off than he was before his accident. This case Professor Fawcett believes to have been reported in one of the periodicals of the time. In reply to Mr. H. Jackson Burrows's letter (p. 418), warning against removal of the patella in cases of congenitally displacing patellae, it goes without saying, though I should no doubt have stressed the point in my article, that the alignment of the extensor pull must also be corrected by some form of tenoplastic operation. I think, however, that it is unfair to pour cold water on this operation of removal of the patella, as yet in its early days of trial, on the strength of two cases of this rare condition for which excision was carried out. I have seen hernias recur, but I still advise operation, because in the majority success is attained. The objection that hyperextension is apt to occur is too mythical to controvert. Dr. P. W. Hampton (March 5, p. 539) has forgotten his physiological teaching as regards the reciprocal innervation of muscles: also the crucial ligaments, as every sportsman knows, will take any amount of strain before snapping. In arthritis, where some atrophy of the crucial ligaments may be expected, there is also reflex wasting of the muscles about the joint, so that hyperextension is again unlikely. I am surprised, however, that more correspondents have not commented on what I consider the most important application of this operation of excision of the patella—namely, to relieve the pain in early cases of osteo-arthritis. This, to my mind, is where the future usefulness of this operation lies.

—I am, etc.,

London, W.1, March 7.

G. O. TIPPETT.

* Perhaps the case to which Mr. Tippet refers as being recorded "some forty years ago" is that described by Dr. James Altham of Penrith in the *British Medical Journal* of May 24, 1890, at page 1190. The case was one of a compound comminuted fracture of the patella with avulsion of the ligamentum patellae. The patella was excised, and ten months later "the patient could walk with perfect freedom and confidence, could go up and down stairs as usual, and was able to ride on horseback."—Ed., *B.M.J.*

Cause of Chronic Gastric Ulcer

SIR.—The statement I read in a medical journal a short time ago that "the cause of chronic gastric ulceration is still quite unknown" prompts me, rather diffidently, to suggest a cause, and a method of treatment that I have been using in practice with good results for about a year.

When I was a student I was taught that chronic ulceration of all types could be subdivided into tuberculous, syphilitic, varicose, etc., and that treatment depended on the cause. We all know that the ordinary chronic gastric ulcer is not syphilitic and not tuberculous, and is not due to any germ isolated to date; but is there any reason why it should not be regarded as a chronic varicose ulcer?

Thousands of years ago man, struggling upwards in the process of evolution, assumed the erect posture, and since then his heart and blood vessels have had to adapt themselves, often failing in the task, to the fact that there is a natural tendency for the blood to stagnate in dependent areas. So we get varicose ulcers of the legs, which caused so much misery until the genius of Mr. Dickson Wright showed us the proper way to treat them. So we get haemorrhoids—the pull of gravity on the contents of a loaded rectum in the upright position must be considerable. And so it is not feasible that we get a tendency to varicosity of the stomach, no longer resting on the abdominal wall, as in animals, and probably also given far too much work to do in digesting too heavy and unsuitable food?

Once it is admitted that the term "chronic gastric ulcer" means "varicose ulcer of the stomach," a host of minor puzzling points become clear. We see now the comparative failure of the alkaline treatment in its proper perspective—the usual hyperacidity is only secondary to the main cause. We see afresh the overwhelming importance of rest, overshadowing, as we have always known, all other treatment. We understand the obstinacy of these ulcers, their world-wide distribution, and their tendency to bleed. We appreciate the failure of excision to cure them and the comparative failure of gastro-enterostomy. And we see now why an experimental ulcer produced in a dog's stomach never remains chronic but heals quickly as soon as the dog is given its liberty. I leave wiser and more skilled heads than mine to do the same sort of experiments on normal and ulcerated stomachs that Mr. Dickson Wright did on normal and ulcerated legs, but I shall be surprised if they do not show the same extraordinary venous stasis.

The treatment I give my patients on this hypothesis is simple. They are put to bed on the usual milk diet, and the usual alkaline powder given if it agrees, otherwise they get no medicines at all. The foot of the bed is raised by at least six inches, and that is all. It is useless for me to say that the ulcer heals any more quickly under this treatment, as every physician knows how impossible it is to dogmatize, and without the control of x rays I am working in the dark. But the results have at least been promising, and I suggest to others to try this simple method, especially on those large ulcers of the lesser curvature that are the despair of physicians and surgeons alike. After-treatment is most important. The foot of the bed should be raised for the rest of the patient's life. At every opportunity the patient should elevate his legs at least to the level of his abdomen. Food should be small in amount but taken often and easily digested.

I am, etc.,

Corwold, York, March 8.

WILLIAM MCKIM.

Appendicitis in Tristan da Cunha

SIR,—I have read with great interest the article by Dr. A. M. Spencer on the aetiology of acute appendicitis in the *Journal* of January 29 (p. 227). There is, however, one small point to which I should like to draw attention.

Dr. Spencer says: "The disease is also very common among the inhabitants of Tristan da Cunha, who live on an exceptionally low cellulose diet owing to the impossibility of growing cereals on the island." Tristan da Cunha has now been inhabited for over a hundred years and earlier medical history is scanty. During this century, however, it has been visited on numerous occasions by ships of the Royal Navy. Since the war a systematic examination of all the islanders has been done on three occasions. I myself was present at the last of these. Medical notes have also been made by the doctors of exploring expeditions and the resident missionaries. Several of the latter have published books of reminiscences, and make no reference to appendicitis, a disease which is well recognized by laymen. The register of deaths is not very accurate, especially as regards diagnosis, as the islanders keep it themselves during the periods when there is no missionary. I have been able to find no record of a death from anything resembling peritonitis, and there is no record of any laparotomy ever having been performed. In the report of the medical examination in 1932 the senior medical officer stated: "One man showed symptoms which might have been due to chronic appendicitis. He was advised to leave the island and be operated upon." He did not act on this advice, and when seen by me at the next examination five years later was alive and well and had no complaints.

During the examination of 1937 I formed the opinion that the physique of the islanders was vastly superior to that of the "civilized" world. There were no complaints or signs of anything resembling appendicitis. The only abdominal pain complained of appeared to be a seasonal gastro-enteritis, which coincided with the sea-bird egg season. At this time the islanders are accustomed to have not one "egg to their tea," but many. It would hardly seem accurate, therefore, to say that appendicitis is very common in a community in which there has never been a death from peritonitis, never been an operation for appendicitis, never been any complaints resembling it (except for the one case quoted above) over a period of more than 100 years.

With regard to the cellulose question, no cereal is grown on the island and potatoes take their place. Adequate and recently increasing supplies of onions, turnips, carrots, leeks, and cabbages are grown and eaten, and as constipation is unknown it would not appear that the islanders are suffering from any serious lack of cellulose.—I am, etc.,

H. E. B. CURJEL,

Surgeon Lieutenant Commander R.N.

Royal Naval Hospital, Simonstown,
South Africa, Feb. 24.

Infantile Pyloric Stenosis

SIR,—Dr. Leonard Findlay states in a letter published in the *Journal* of March 5 (p. 538) that "Mr. David Levi . . . would seem to have overlooked the fact that by the use of eumydrine or other antispasmodic, hospitalization of the infant . . . becomes unnecessary." This I would deny. Svensgaard's original instruction when treating patients with eumydrine was that the child should be rehydrated. He says that the child should be put on subcutaneous salines until diuresis demonstrates that the dehydration has been overcome. Does Dr. Findlay

propose carrying out these methods in the out-patient department or at home, or has he a new approach to treatment which he has not yet published? I have yet to meet the physician who treats all cases of pyloric stenosis as out-patients. My medical colleagues tell me that with eumydrine a prolonged period of hospitalization is usually necessary, and I know that this is the general experience. I cannot, of course, speak from my own practical knowledge of this method of treatment as I have never used it, but I have been called to rescue its failures. In the last thirteen weeks I have operated on twenty-eight patients suffering from pyloric stenosis, and in the course of a year I see a very large number of cases.

I have come to the conclusion that no deduction of any moment can be drawn from a small series of cases, such as the six patients quoted by Dr. Findlay. A similar series can be produced to show the value of thickened feeds, or of careful feeding and gastric lavage without any other form of medication. I felt that I had to answer Dr. Findlay's statement on hospitalization, which is inaccurate, but I will pass over his mention of "the radiological findings, which of all the signs of the disease are the most fallacious," as an expression of an opinion which is not universally accepted.—I am, etc.,

London, W.1, March 6. DAVID LEVI, M.S., F.R.C.S.

Diverticulitis of the Caecum

SIR,—I read with interest in the *Journal* of February 26 (p. 475) your summary of the paper on solitary diverticulitis of the caecum, read by Mr. Bennett-Jones to the Liverpool Medical Institution. The fact that he was able to bring four cases of this disease to the notice of the society is evidence that the disease is not so rare as previously recorded cases—seventeen in all—would suggest. Probably there are others like myself who have come across the condition and have omitted to publish their cases.

It will be readily appreciated that when a solitary diverticulum of the caecum becomes inflamed the condition is difficult to distinguish from acute appendicitis.

In July, 1934, I was called urgently to see a doctor, aged 35, suffering from severe abdominal pain. The pain, which had begun the previous day, was at first located in the mid-abdomen and later settled in the right iliac fossa. There was tenderness and rigidity over the lower abdomen, but these signs were most marked in the caecal region. He had been seen by three of his colleagues, and there was little doubt in all our minds about the diagnosis. At operation I found diffuse sero-purulent exudation due to a perforated caecal diverticulum. The diverticulum was situated on the anterior surface of the caecum, close to the ileo-caecal junction, was barely three-quarters of an inch in length, and had perforated near the tip. There was no inflammation of the appendix. Both the diverticulum and the appendix were removed, the abdomen was drained, and the patient made a good recovery.

When perforation of a diverticulum of the caecum is localized by surrounding structures the condition enters on a chronic phase and gives rise to more confusion in diagnosis—for example, appendix abscess, tuberculosis, carcinoma, etc. As Mr. Bennett-Jones remarks, diverticulitis is always considered when disease of the left side of the colon is under consideration, but rarely considered when dealing with the right side. In the light of after-events I am inclined to think that a case with which I had to deal six years ago and which at first was thought to be carcinoma or tuberculosis of the caecum was really one of diverticulitis.

The patient was a female aged 28 whose appendix had been removed a year previously through a small muscle-splitting incision in the right iliac fossa. The operation afforded little

of milk will not cure the tuberculosis, scarlet fever, and other conditions mentioned in the advertisement; it will not even help appreciably while unsafe butter is allowed to go unnoticed.—I am, etc.,

Merioneth, March 5.

EMER JONES.

Pneumonitis

SIR,—I wonder if the first of those American authors to coin the word "pneumonitis" thought that he was "saying a mouthful" and carrying our knowledge further. This alleged new entity, with ghostly appearances in the x-ray film but with no exactly discerned pathological basis, is to be pinned down to earth with what looks like a scientific label. But why not substitute the simpler term "inflammation of the lung"? That would at least discourage the clinician from deluding himself, as he looks at a radiograph darkly, into thinking that now he sees face to face some new disease. "Annotations have appeared in the *Lancet* (1937) and in the *British Medical Journal* (1937)," the article would then read: "and X. and Y. now recognize inflammation of the lung as a separate entity." *Parturient montes, nascetur ridiculus mus!* The physician who learns much from radiographs of the lungs can only interpret clinical pictures in terms of x-ray appearances if both these have already been integrated with and interpreted by a knowledge of the underlying pathology. Is there some new, hitherto unrecognized pathological process which produces these particular inflammations of the lung?—I am, etc.,

Liverpool, March 8.

ROBERT COOPE.

Pure English

SIR,—Dr. D. T. Barry. I think, does well to be dissatisfied with the word "sympathicolysis" (*Journal*, March 5, p. 544). "Sympathicolysis" is a very doubtful formation, but it might possibly be wrested to mean "dissolution of a partner in unnatural vice." It has the advantage of keeping its meaning "veiled," as Gibbon said, "in the obscurity of a learned language": on the other hand, it comes in queerly under the heading of "Pure English," and, moreover, it is not what Dr. Barry means.

Near it in your correspondence columns occurs that congenital defective "contraception": as to which it seems to me that if "sympathicolysis" has a meaning, though an unsavoury one, "contraception" has none at all. However, having escaped its appropriate fate of being strangled at birth, "contraception" is, I fear, a monster now too robust to perish. But there is a third specimen of more tender years which is possibly not beyond the resources of orthopaedics—"achresthic anaemia." This type of anaemia is defined as one in which the patient is unable to make use of the anti-anaemic factor, and though ἀχρηστικός usually means "incapable of being used," it has a rare active use and may mean "making use of." But why not "achrestic"? Whence the second aspirate? Is the well-known verse quoted by St. Paul responsible—*ῥεῖμασαν ἡφ' ἡμῶν ὁμιλίαι κακάς*, "Evil communications corrupt good manners," where the final *r* has received the aspirate from the ὁμιλίαι following it? Is it too much to hope that if there is another edition of Osler's *Principles and Practice of Medicine* "achrestic" may become "achrestic"? Osler had a conscience in these matters, even though he did always spell aneurysm with an "i."

Many years ago a wise man, possibly Sir A. Quiller-Couch, suggested that if the dead languages were lively enough to provide scientific terminology for modern ones that could not, it might be as well for the scientists to consult the scholars before committing themselves to print.

In fact we ought to treat the language of Hippocrates with respect: though if he, sitting beneath a ghostly plane tree in the place to which good physicians go, is still conscious of "The Art," he is probably smiling benignly. Galen at any rate could bring him up to date on the second century implications of "pathicus."—I am, etc.,

Barrow-in-Furness, March 7.

JOHN WARE.

Correct Footwear

SIR,—Looking into a shoe shop the other day I was struck by the type of some of the ladies' shoes. These had the toe-cap cut away on the medial side so as to expose the (painted) nail of the great toe. It seemed to me that a very slight modification of this fashion might be taken advantage of, and a shoe devised which would allow the great toe to develop in the direction which Nature intended and which in fact is normal in the barefooted races. To attain this object two conditions would be necessary: (1) the great toe would have to be completely exposed on the medial side as far back as the base of the proximal phalanx; and (2) the fashion in this type of shoe would have to be set by persons sufficiently influential to ensure a wide following for it. In respect of the latter, the medical profession, especially the women doctors, might discharge their duty and responsibility to the public and their own sex, as suggested by Dr. Margaret Emslie (*Journal*, March 5, p. 544), by themselves wearing such shoes, though a still more impressive argument might be advanced if the president and members of the British Orthopaedic Association could be induced to set the example! Speaking seriously, if the whole of the great toe could be allowed to grow without restraint in the first ten years of life, during which time the personal factor counts for little, many of the disabling deformities in this region might be avoided.—I am, etc.,

Belfast, March 7.

S. T. IRWIN.

Treatment of Plantar Warts

SIR,—The incidence of plantar warts in adolescent school children, mentioned by Dr. R. M. B. MacKenna in the *Journal* of March 5 (p. 509), raises the question of the best and most rapidly effective method of treatment. Treatment by radium and x rays both necessitate the services of an expert, and in spite of the advantage of painlessness a very large number of parents would be unable to afford such treatment. In addition, I have seen one case which had received x-ray treatment in which the warts were unaffected, though a dermatitis was present. Treatment by local escharotics and keratolytics is very tedious, many applications are necessary, the end point at which treatment should cease is by no means clear, and some sort of dressing is needed throughout, but it has some value in the "seedling" stage. In school practice I consider that excision, or more correctly "curettage," is by far the best and most effective treatment. Dr. MacKenna, in his article, tends rather to condemn the method with faint praise, and states that it may be "attempted" if physiotherapeutic measures are not available. The disadvantages of the method, as he points out, lie in the necessity for either a general anaesthetic or a very painful local anaesthetic injection.

In cases where one or two warts only are present infiltration with 1 per cent. novocain is nearly always possible. Adolescent children, especially girls, are wont to show a remarkable degree of fortitude in regard to these injections. The special pain of puncture and infiltra-

Acriflavine Emulsion

SIR,—Dr. J. Walker Tomb's letter (*Journal*, January 29, p. 256) describing an alternative formula for acriflavine emulsion raises some interesting points. The formula he suggested was as follows:

Acriflavine B.P.	1 gm.
Lime water B.P.	500 ml.
Olive oil B.P.	500 ml.

Professor L. P. Garrod and Mr. G. L. Keynes, in their article on the use and abuse of antiseptics (December 25, 1937, p. 1286), criticized the B.P.C. emulsion in regard to its high oil content. In the light of this criticism the above formula represents an improvement on that of the B.P.C. in that it contains less oil and more water. Dr. Walker Tomb mentions the enhanced action of acriflavine in an alkaline medium, and I presume he intends his emulsion to have an alkaline reaction. This will probably be so when using B.P. edible olive oil (acid value not more than 2.0), because it can be calculated that the alkalinity of lime water is neutralized by an equal volume of olive oil when the latter has an acid value of approximately 2.5. On the other hand, it should not be forgotten that for external preparations, such as oily liniments, the B.P. recognizes olive oils possessing acid values not exceeding 6.0. In view of this some confusion may arise, and it will depend largely upon the choice of oil as to whether the finished emulsion is alkaline, neutral, or acid in reaction. Moreover, if lime water emulsions of acriflavine became popular circumstances might arise when it would be very convenient to keep a "stock" ready made. This would create a further difficulty in the case of the formula under discussion, because such a "stock" mixture would eventually become acid, due to the progressive hydrolysis of the glycerides in the olive oil. May I therefore suggest a modification which would preserve the usefulness of the formula and at the same time free it from the disadvantages described—replace the olive oil by liquid paraffin containing enough oleic acid to form a soap with the calcium hydroxide of the lime water, but leaving an excess of the latter sufficient to give the finished product the desired alkalinity. In this way an emulsion is obtained which is simple to prepare, reasonably stable, and cheap. The formula is as follows:

Acriflavine	0.1 gm.
Solution of calcium hydroxide	60 ml.
Oleic acid	0.5 ml.
Liquid paraffin	40 ml.

The lime water, of course, should be freshly prepared. Although the proportion of oil is purposely as small as possible, more than sufficient is present to provide lubrication and to prevent dressings from sticking. The viscosity of the emulsion when made with B.P. liquid paraffin is fairly high, and if desired a more mobile and less expensive product can be obtained by using a good-quality oil of lower viscosity, such as is used in the preparation of nebulae for spraying the nose and throat. At this hospital good results have been obtained with an oil of specific gravity 0.850, 50 ml. of which at a temperature of 37.8° C. flow from a Redwood No. 1 viscometer in not less than 70 and not more than 75 seconds. The oil complies also with the limit tests for sulphur compounds and acidity described under the B.P. monograph for liquid paraffin. Although there is some tendency for the finished emulsion to separate on standing, homogeneity is quickly and easily re-established by shaking.—I am, etc.,

Liverpool, March 5.

Raw or Pasteurized Milk

SIR,—The letter of Dr. Bernard Myers (*Journal*, March 5, p. 537), and the evidence he quotes regarding the danger of raw milk and the safety and nutritive value of pasteurized milk, should surely convince even the most complacent as to the urgent necessity for strong action being taken immediately by all those responsible for our milk supplies—including the Government. One of the chief reasons for delay is, I believe, the lack of uniformity of opinion in our hospitals and in the medical profession. Many hospitals provide their patients with ordinary raw milk, which is neither pasteurized nor sterilized by boiling, and they do not buy milk from a tuberculin-tested herd even in localities where such milk is easily obtainable. Many doctors still advise the consumption of raw milk with the object, they say, of developing immunity in the children who drink such milk. Some, the "whole-hoggers," advise all raw milk from the start. "Let the child take its chance," they say; "the sooner it develops immunity the better"—truly a policy of kill, cripple, or cure. Others adopt what they fondly imagine is a more scientific method. They start the child on milk from tuberculin-tested cows, and gradually replace such milk with increasing quantities of ordinary raw milk. One wonders how they estimate the dose of tubercle bacilli—presumably by the pint or half-pint!

In our campaign for pure and safe milk supplies do not let us forget, or fail to draw attention to, the danger of acquiring other diseases from infected milk. Many epidemics of scarlet fever and of typhoid have been traced to infected milk; and what of undulant fever? Many of our herds are infected with *Br. abortus*, the proportion of infected cows varying from 10 up to 50 or 60 per cent. and over. Consider the deaths of children under 2 years from infective enteritis or diarrhoea. According to the figures published in the epidemiology section of the *Journal*, sixty or seventy children are at present dying weekly from this disease in the 125 great towns in England and Wales alone. Nothing is more certain than that these figures will be enormously increased in the summer months. I believe I am right in expressing the opinion that many of these deaths and much misery and unhappiness could be prevented were these children to be given sterilized milk.

One word of criticism. Why does Dr. Myers write of "tuberculin-tested milk"? There is no such thing. One often hears milk from tuberculin-tested cows so described, and the designation "tubercle-free milk" is also often used. The tuberculin test is not infallible, and such loose phrases create in the consumer a false confidence and security. The only milk which can be correctly described as "tubercle-free" is that which has passed a thorough bacteriological examination.—I am, etc.,

Dundee, March 5.

F. R. BROWN.

Safe Milk and Safe Butter

SIR,—I have been interested in the Association's advertisements and most pleased to see publicity being given to such an important question. It is a pity that the advertisement has not been more carefully prepared. It contains one very grave mistake; it says: "About 2,000 deaths a year in Great Britain are due to bovine tuberculosis, a disease which is carried by unsafe milk." Bovine tuberculosis is caused by unsafe butter as well as by unsafe milk, and as the plea of the advertisement is to purify the milk and not to test the herds, I feel that this paragraph should be altered. Boiling, pasteurizing, etc.,

OBITUARY: SIR RAYMOND CRAWFURD

Obituary

SIR RAYMOND CRAWFURD, M.D., F.R.C.P.
Consulting Physician, King's College Hospital Registrar, Royal
College of Physicians of London

Sir Raymond Henry Payne Crawford, who died on March 9, was born November 9, 1865, the son of the Rev. C. W. Payne Crawford of East Grinstead. He was educated at Winchester and New College, Oxford, graduating B.A. in 1889, and in the same year entered the Medical School of King's College Hospital as its Warneford scholar. In the history of "King's" he is described as being by far the most brilliant student of his year, and he was awarded the junior and senior scholarships of the school in 1891 and 1894. He qualified for practice in 1894 with the M.B., Ch.B. of Oxford and the M.R.C.P. diploma. He then held resident posts at King's College Hospital, and after their completion he was appointed assistant physician to the Victoria Hospital for Children and to the Royal Free Hospital, which he served from 1896 to 1908. He lectured on materia medica and pharmacology at the London School of Medicine for Women and on pathology at the Royal Free Hospital.

In 1898 Crawford was elected assistant physician at King's College Hospital, and remained in active work there until 1930. In the course of time he became a prominent member of the teaching staff of the medical school, first as lecturer on materia medica and pharmacology, and later in clinical medicine and as director of medical studies. He exercised great influence for the good in the advancement of the hospital and school, and was mainly instrumental in getting the Burney Yeo bequest scholarship in 1914. He was an attractive teacher, and King's College prided itself on one of its pupils gaining the Murchison clinical scholarship—awarded in alternate years by the Royal College of Physicians of London and the Edinburgh University—in four successive examination years, when it was open to competition in London, 1922-8. He wrote many papers for medical literature, Graves's disease especially interesting him and being the subject of his M.D. thesis (1896). He also contributed articles on it to Quain's *Dictionary of Medicine* and to his hospital reports. In 1914, with Sir Farquhar Buzzard, he edited the fifth edition of Burney Yeo's *Manual of Medical Treatment*, its author being too ill to face the task. Buzzard revised the chapters on nervous diseases and Crawford the rest. Later editions were called for.

Raymond Crawford's first historical work appeared in 1909, and was on the *Last Days of Charles II.* In this he reviewed the eight existing descriptions of the illness by eye-witnesses. One of the most important was that of Sir Charles Scarborough, physician to the King. The original—in Latin—is in the possession of the Society of Antiquaries, and Crawford gives a complete copy of this with a translation. It was prepared by Scarborough chiefly to combat the rumour that the King had been poisoned.

Macaulay and others attributed the death to apoplexy. By an examination of all the reports side by side a striking common line of agreement was to be found in them, and led to the clear conclusion that the final illness was uraemic convulsions brought on by chronic nephritis, probably of gouty origin. Crawford's story is a bald statement of facts, confined to the medical aspect of the illness, and it is interesting to read of all the remedies used—bleeding, blistering, pills, and potions. There is also an account of the priest Hudleston's administration of the last rites of the Roman Catholic Church, and of the King's acceptance of its faith.

Crawford took an active part in the work of the Royal College of Physicians, of which he became a Fellow in 1901. He delivered the Fitzpatrick Lectures in 1911-12, and the Harveian Oration in 1919. He was one of its examiners and councillor in various years, and became Registrar in 1925. The Fitzpatrick Lectures on "The King's Evil" were published in an ampler form as a book with illustrations of a broadside of the ceremony and office of "healing," issued in 1679; of various kings presented to the sufferers from the evil. The term scrofula had various meanings at different times. It was scrofula had various meanings at different times. It was the form of "struma" that affected the neck and enlarged it to look like that of a sow—*scrofa* of Latin writers. Its meaning to-day is uncertain, unless, as Crawford says in his preface, we may fall back on the French *mor*: "On devient tuberculeux, mais on nait scrofuleux." It is a handsome presentation of the subject, but like other of his works sadly lacks an index.

The Harveian Oration was on the forerunners of Harvey in antiquity. The orator thought when he came to examine the outstanding accounts of the history of the discovery of the circulation that too little had been conceded to the master minds of antiquity, especially Aristotle's doctrine of the primacy of the heart. He found an interesting parallelism in the lives of Harvey and Aristotle and their court appointments, etc., and he reviews fully Aristotle's work and opinion on the heart and blood vessels. The researches of Erasistratus and Galen are also considered; all in an interesting and novel a manner as could be expected from about the two hundred and fiftieth Oration. Another historical work published in 1914 was on *Plague and Pestilence in Literature*. The words "and Art" might have been fairly added to the title, for the book contains many reproductions of pictures by various Continental artists of plague-stricken peoples and towns. The Great Plague of London comes in for some descriptions, but there is no illustration of it. The work is more a general than a medical account of plague, and does not deal with anything after the end of the eighteenth century.

Crawford took an active and enthusiastic part in the administration of Epsom College, and for several years was chairman of the council of governors. He received the honour of knighthood in 1933 for his distinguished services to medicine.

Sir Raymond Crawford had been a member of the British Medical Association since 1897, and at the Centenary Meeting in 1932 he acted as vice-president of the Section of History of Medicine. At the memorial service, held at St. Martin-in-the-Fields on March 15, the Association was represented by Dr. Geoffrey Marshall.

Sir Humphry Rolleston writes:
Educated at Winchester and New College, Oxford, Crawford retained their scholarly impress, and it was in such an atmosphere that we first met in 1891 at the house in

tion is apparently due to the denseness of the tissues concerned, and the sensitiveness of the plantar surface of the sole and toes. The initial injection may be made tolerable by the use of a No. 16 needle with a short bevel, sterilized by boiling in olive oil. The initial puncture is made slowly, injection being started very gently as soon as the bevel is hidden, and continued slowly until the base of the wart and all the area which can be reached through this puncture have been infiltrated. Further punctures are usually painless. Freezing with ethyl chloride before the initial puncture is not advised, since the small operation area is altered in appearance, and many warts are much more appreciable to touch than to sight.

If the warts are multiple, or for some reason local anaesthesia is impossible, a general anaesthetic becomes necessary. In these cases it is advisable to prepare before operation a plan indicating the number and exact position of the warts. Enucleation of the warts with a Volkmann's spoon, or, if small, with a meibomian cyst scoop, if carried out by the method originally described by J. L. Franklin (*Practitioner*, 1932, 129, 506) will give excellent results, and a local recurrence should be exceptional.

In cases dealt with under local anaesthesia after-pain may be mitigated by filling the wart cavity, after haemostasis has been effected, with anaesthetin, 15 per cent., in ammoniated mercury ointment. After general anaesthesia a light gauze dressing only is necessary. Except in cases of multiple warts, walking may be allowed as soon as it is certain that no reactionary haemorrhage will occur, and school work will not be interrupted for a single day, though games and routine walks should be forbidden till healing is sound. The cavities often heal very rapidly: after local anaesthesia in from ten to fourteen days; after general anaesthesia sometimes in less than a week. There is no special tendency to sepsis.—I am, etc.,

Rustington, Sussex, March 8.

W. E. WALLER.

Early Occurrence of High Blood Pressure

SIR,—In her paper on the early occurrence of high blood pressure in coarctation of the aorta (*Journal*, March 12, p. 564) Dr. E. Joan Rooke states that in 1933 the youngest case then on record was a boy of 14 who had coarctation of the aorta and a blood pressure of 150 mm. Hg. If Dr. Rooke will turn to the *Archives of Disease in Childhood* for December, 1929, she will find a full account, together with a description of the partial necropsy, of the case of a child aged 5 which I recorded with F. W. M. Lamb. In our paper there is an account of the study of the systolic blood pressure, which was consistently over 200 mm. on the left side and varied between 175 and 215 mm. on the right. In my case unsuspected diffuse arteriosclerosis was found, which was not limited to the vessels exposed to the high blood pressure. In addition there was a congenital abnormality of the left kidney with diffuse sclerosis. It was not clear what part these changes played in determining the high blood pressure, but inasmuch as the systolic pressure in the popliteal arteries was only 125 mm. it was probably not a great one.—I am, etc.,

Birmingham, March 12.

A. P. THOMSON.

SIR,—A statement in the *Journal* of March 12 (p. 564), issued from the Department of Clinical Research of University College Hospital by Miss E. Joan Rooke, seems to be open to criticism. She states that some murmurs heard on both sides of the sternum resulted (*sic*) from enlarged internal mammary arteries. It would be interesting to know what is meant by such a statement. We

are given both the "systolic" and "diastolic" pressures in the right arm, but only "the pressure" in the left arm. Was this the "systolic" or the "diastolic"? If it is the "systolic," what was the "diastolic"? The writer tells us that the demonstration of high blood pressure in the child is important because it occurs at a period of life when high pressure from other causes is extremely rare. Is this her experience, or is it given on any authority? My experience, in acute rheumatism especially, is that both the "systolic" and what I call the "basic" pressure are raised before an attack and tend to fall as the attack disappears.—I am, etc.,

Swansea, March 12.

G. ARBOUR STEPHENS, M.D.

Iron for Subnutrition

SIR,—Drs. E. Blackstock and J. M. Ritchie, in your issue of March 5 (p. 512), report their observations on a group of anaemic children selected from those attending a welfare centre. The diagnosis in each case was proved by complete blood examination, and there was a satisfactory response to iron therapy. These infants were selected because on clinical examination they were considered anaemic, and it is quite certain that in many centres they would not have had the benefit of treatment. I would emphasize, however, that much iron deficiency is overlooked when full reliance is placed on physical examination. The high incidence of iron deficiency has been stressed by many workers in recent years, and until adequate preventive measures are adopted I would urge that a haemoglobin estimation be carried out on all children attending pre-school centres.—I am, etc.,

London, W.1, March 10.

THOMAS COLVER.

George Buckmaster and William Wright

SIR,—The Executive Committee of the Council of the Royal Australasian College of Surgeons is grateful to Mr. Gordon Gordon-Taylor, F.R.C.S., for his expression of the sorrow which is felt in Australia and New Zealand at the death of Professor G. A. Buckmaster, D.M., F.R.C.S., Emeritus Professor of Physiology, University of Bristol. Professor Buckmaster was loved by all those members of the profession in both Australia and New Zealand who were privileged to meet him on the two occasions on which he visited these countries. His visits did much to cement the bonds of unity between the members of the surgical profession in Australia and New Zealand and their brothers in Great Britain.

Similar feelings exist in regard to the late Professor William Wright, who was Professor Buckmaster's colleague as Examiner in Anatomy in Melbourne in 1931. The deaths of these two men are deeply deplored by everybody in Australasia who knew them.—I am, etc.,

H. G. WHEELER,

Secretary, Royal Australasian College
of Surgeons.

Melbourne, Feb. 25.

X-Ray Film Developing Box

SIR,—I was pleased to see that Mr. Robert G. W. Ollerenshaw has paid tribute to the use of the x-ray film developing box during the operation on fractures of the neck of the femur by the introduction of a Smith-Petersen nail (*Journal*, March 12, p. 569). We orthopaedic surgeons in London are greatly indebted to Mr. D. W. Atkinson, the radiographer, who is, I understand, the inventor of this process of rapid development of the film, thereby very greatly diminishing the total amount of time taken over the operation.—I am, etc.,

B. WHITCHURCH HOWELL, F.R.C.S.

London, W.1, March 13.

MARCH 19, 1938

OBITUARY SIR ARTHUR DOWNES

Sir Arthur Downes was knighted in 1910 and received the Order of the Crown of Belgium. He took pride in recalling that his work published between 1877 and 1886 on the influence of light on bacteria and on protoplasm was the earliest research to reveal the destructive action of light on the micro-organisms of putrefaction and disease.

Sir Arthur MacNalty writes:

Last week witnessed the passing of two great gentlemen, Sir Raymond Crawford and Sir Arthur Downes. Their professional reputations were achieved in different branches of medicine: Sir Raymond was pre-eminently a physician and medical historian, Sir Arthur won distinction first in medical research and afterwards in the field of public health and as a medical administrator. Yet they had this in common: they were both men of good will and considerate to all whom they met. In these hurried and strenuous days people are sometimes impatient of attention to the feelings of others. Good manners may be attributed to artificiality. In these two men their courtesy was an index of their infinite kindness of heart.

Although there were links of old association between the Downes family and my own—my grandfather's Christian names were "Arthur Downes"—I first met Sir Arthur in 1908 when he was a member of the committee of the Brompton Hospital for Consumption, to which I was then resident medical officer. Not only was I impressed by his wise counsel in matters affecting the administration of the hospital, but his advice to the committee on medical subjects was equally sound and valuable. When I left the hospital our friendship continued, and, subsequently, as a medical inspector of the Local Government Board, from time to time I came once more into official relations with him. He had a profound knowledge of the Poor Law and of the nursing services, and in his usual quiet and unobtrusive fashion he rendered great service to the Department. He was a member of the Royal Commission on the Poor Law, and if his counsels had prevailed the Poor Law would have been reformed twenty years earlier. His work in public health in Shropshire and Essex respectively early marked him out for distinction. He wrote to me in 1935:

"What a vast change has come over public health administration since 1876 when I deputized as M.O.H. for the old Shropshire Combined District of some twenty-one rural or urban sanitary authorities and when I took my Cambridge D.P.H. (at first known as the S.Sc.Cert.Camb.) in 1877 or 1878. I rather think I must be the doyen of D.P.H."

"Curiously enough a 'tightness' in the finances of Cyprus (in Turkish days) deprived me of a chance of joining the medical side of the L.G.B.: I had been invited to apply by the elder Sir George Buchanan, but just when my opportunity came it became necessary to find a place for Cyprus who had greatly distinguished himself first as a M.O.H. in the north of England, then as a Sanitary Commissioner for Cyprus during British occupation). But, as I have said, chronic Turkish deficits 'axed' him. I had previously been invited by Simon to come to see him, but, being in the country, failed to avail myself of it. Of the immense improvement in the public health of England since those days there can be no question."

Downes's papers in the *Proceedings of the Royal Society* on the effect of light on bacteria and protoplasm, published many years ago, reveal him as a pioneer in medical research. He was the first to demonstrate the destructive action of light on the organisms of putrefaction and disease. So valuable was Sir Arthur's advice to the Local Government Board that his services were

retained beyond the usual age of retirement. When at length he left us he did so with the affection and regret of all his colleagues. Sir Arthur had a delightful sense of humour and was a charming host. He had many interests in life, such as the development of nursing of the sick poor and the care of lepers. But he was also well read in general literature and I have many letters from him which reveal his knowledge of archaeology and natural history.

On retirement he lived in France for several years, and finally fixed his habitation on the top of Mount Carmel in Palestine. But as he wrote to me recently: "For a man in his 86th year there cannot be much prospect of an 'abiding city' on earth." The words of Greville concerning Sir Philip Sidney are truly applicable to Arthur Downes, and I cannot sum up his character in better words: "Indeed, he was a true model of worth: . . . withal, such a lover of mankind and goodness that whoever had any real parts in him, found comfort, participation and protection to the utmost of his power."

RICHARD HUXLEY FISH, M.D., M.R.C.P.

We regret to record the sudden death on February 15, from subarachnoid haemorrhage, of Dr. R. Huxley Fish, at the untimely age of 32, when he had held the post of physician to Harefield Sanatorium for but a very few months. The only son of Dr. Cecil Fish, who died when he was a boy, Huxley Fish was educated at Bedales School and at Clare College, Cambridge, where he was a scholar. Dr. Fish gained first-class honours in the Natural Sciences Tripos in 1927, and proceeded to St. Thomas's Hospital, where he qualified in 1930; he took the M.R.C.P. in 1932, graduated M.B. of Cambridge in 1934 and M.D. in 1936, and took the diploma in child health in the same year. He was house-physician and children's house-physician, as well as holding other resident posts, at St. Thomas's Hospital, and then became assistant medical officer to the L.C.C. High Wood Hospital for Children at Colindale. Later he was senior assistant medical officer at Colindale Hospital until his appointment as physician under the Middlesex County Council. Dr. Fish had already made his mark in the specialty of tuberculosis, where he was recognized as perhaps the most distinguished of the younger men. He was possessed of a very unusual charm, devoted to him. He wrote on the treatment of chorea by induced pyrexia in this *Journal* in 1933, using intravenous injections of a triple typhoid vaccine with successful results. In 1937 an annotation appeared in our columns (May 1, p. 925) on his monograph in the *Archives of Disease in Childhood* (1937, 12, 1) on chronic miliary tuberculosis in children; this monograph confirmed the work of previous investigators that there is a chronic form of miliary tuberculosis which is not necessarily fatal, and in the treatment of which absolute rest is all-important. From the quality of his work, which showed him to be a careful and earnest physician, his early death is all the more to be regretted, for he left a mass of material ready to be polished into final form. He leaves a widow and three little sons, to whom goes out the sincere sympathy of all who knew him and had such high hopes for his future.

Dr. SARA E. WHITE, who died on February 10, aged 82, was born in Ireland of Quaker stock. She came to London to study at University College, and took the B.Sc. in 1891, with honours in physiology, in which subject she was for a time a demonstrator. She soon, however, decided to follow in the footsteps of her cousin,

Gordon Street of his relative, Dr. William Ogle, the superintendent of statistics at the General Register Office, translator and annotator of Aristotle's *On the Parts of Animals* (1882), and the third son of J. A. Ogle, Regius Professor of Medicine at Oxford from 1851 to 1857. Crawford was that admirable, though somewhat unusual, combination of the scholar-physician with the first-rate man of affairs, courteous, dignified, reticent, self-restrained, and thus reminiscent of a bygone day. At first his life was that of a young consultant in London, and he contributed to the *Transactions* of the old Pathological Society of London, and in 1909 brought out, with the present Regius Professor at Oxford, the fourth edition of Burney Yeo's *Manual of Medical Treatment*. But he was long handicapped by poor health, which for a time laid him entirely aside, and he gave up the ordinary Harley Street career. On recovery he devoted himself whole-heartedly to three institutions to their great benefit: at King's College Hospital, in the removal of which to Denmark Hill he had played an active part, he took a very practical interest in the school and the students, and the successes of his former house-physicians bear eloquent testimony to his influence. For years the moving spirit at Epsom College, he wrote fifteen hundred personal letters in his clear, characteristic script for an appeal. At the Royal College of Physicians of London he was, since 1925, the ideal Registrar, having previously held high office and delivered the Harveian Oration and the Fitzpatrick Lectures. His contributions to medical history, mainly carried through when physically laid aside, are of widely recognized value, and he was the third president, following Sir William Osler and Sir Norman Moore, of the Section of the History of Medicine at the Royal Society of Medicine, of which he also followed Sir Norman Moore as honorary librarian.

A correspondent writes:

It is no secret that the immediate predecessors of Raymond Crawford in the chairmanship of the Council of Epsom College had displayed neither the energy nor the capacity which he brought to that position; and that the reputation of the College had been definitely suffering in consequence. The thirteen years (1923-36) of his occupation of the chair were a period of reorganization and expansion in every direction: nothing was too small for him personally to inquire into, nothing great enough to frighten him. During this long period he strove incessantly for the improvement of the School and of the Foundation, with single-minded devotion and with outstanding success. For most men the work he did would have been a full-time occupation: but with Crawford it was but one of the many sides of his life. His handling of his Council was tact and discretion itself: if he had a failing as a chairman it may have been that he sometimes allowed undue prolixity in debate; but his quiet persuasiveness and imperturbable good temper made it impossible for anyone to quarrel with him, and his methods probably helped him to get his own way when a stiffer chairman might have failed. Now and then it happened that some reform on which he had set his heart did not commend itself at once to his Council. He would accept defeat without betraying the least annoyance—and then quietly set about a course of judicious lobbying among his opponents which would lead to success a few months later when the particular matter came up again. An instance of his ascendancy over his Council, or rather of the way in which it was built up, was afforded a few years ago, when at the close of a busy afternoon he addressed the members somewhat as follows: "Gentle-

men, I must apologize for bringing up a topic which is not on the agenda, and I hope you will forgive me if you think I have exceeded my functions. I have felt for some time that our Biology Laboratory is out of date, and should be scrapped: Chemistry and Physics are so well equipped now that we must provide equally for Biology, and I have taken the liberty of asking our architect to draw out some plans." The plans were then produced, and when someone asked the probable cost the answer was "About £6,000." On a further inquiry where this sum of money was to come from, the chairman paralysed all opposition by a laconic statement that he had already obtained promises to the extent of £3,200.

Great as were the improvements to the College buildings for which he was responsible, Crawford's keenness on educational progress was greater still: he was more than once known to complain half humorously that he always found it easier to induce his Council to spend money on laboratories than on learning (laboratories was not the word he used, but it is near enough). As recently as the end of February he made, a long speech to the College Council on current trends in secondary-school education packed full of practical wisdom and advice, which his colleagues were eager to accept. He had originally, when resigning the chairmanship, stipulated that he should leave the Council too, probably with a view to making things easier for his successor. It has been a real gain to the College that he was persuaded out of this resolve; he was a member of the Council for twenty-three years in all. When, after his resignation, he was presented by his past and present colleagues, quite contrary to his own wishes, with a piece of suitably inscribed silver plate, his speech in Big School to the assembled Council, masters, and boys was a model of what an oration in such circumstances should be—a masterpiece of simplicity and sincerity, phrased in flawless English.

SIR ARTHUR DOWNES, M.D.

Late Senior Medical Inspector for Poor Law, Local Government Board

We regret to announce the sudden death of Sir Arthur Downes, on March 11, at his home on Mount Carmel, Haifa. He had been a member of the British Medical Association for just on half a century, and in his retirement became a member of the Palestine Branch.

Arthur Henry Downes, son of T. R. C. Downes, was born in Shropshire on October 11, 1851, and from Shrewsbury School went first to University College, London, and then to the University of Aberdeen, where he graduated M.B., C.M., with highest honours, in 1873, and proceeded M.D. two years later. He took the Cambridge D.P.H. in 1877, and soon afterwards entered the public health service, acting for a year as deputy medical officer in Shropshire and then as M.O.H. from 1879 to 1899 for the Essex combined areas. He was then appointed a medical inspector under the Local Government Board, and during thirty years' service was a member of the Royal Commission on Poor Law and Relief of Distress, and also a number of Departmental Committees, including those on workhouse dietaries, nursing in workhouses, workhouse accounts, feeding of prisoners, vagrancy, the Midwives Act, and the condition of the blind. He represented the Local Government Board on the Social Welfare Association for London and the Central Council for District Nursing. He was chairman of the first Committee on Homeless Poor in London, and after his retirement from work in Whitehall became a trustee of Lord Strathcona's charity for lepers.

M.B., B.Ch. degrees in 1894, and the F.R.C.S. in 1895. Mr. Cull's first association with the Sheffield Royal Infirmary was as house-surgeon. He then practised in partnership for some time, relinquishing general practice on his appointment to the visiting surgical staff at the Royal Infirmary. He was for some years lecturer in surgery at the University of Sheffield and an examiner in surgery for the University of Cambridge. From 1898 he had been medical referee for the Sheffield and Rotherham County Court Districts under the Workmen's Compensation Act. During the war he served with the Royal Field Artillery (T.) as surgeon major in France, and a few years after his return to civil life he was appointed a justice of the peace. At the Annual Meeting of the British Medical Association in Sheffield in 1908 he was vice-president of the Section of Surgery.

We regret to announce the death last month, at the age of 84, of Dr. SAMUEL E. MOSTYN HOOPS, in Victoria, British Columbia. After qualifying in Dublin in 1874 he practised for many years at Douglas, Isle of Man, where he was Commodore of the Douglas Bay Yacht Club in 1894, when the *Britannia* and other big yachts took part in the regatta. In 1897-8 he went on an overland expedition from Edmonton to the Klondyke, and never returned to the British Isles. For some years he practised at Soda Creek up the Cariboo Trail in British Columbia, and was coroner and medical officer in charge of the Red Indian Reserves over a wide area. Dr. Hoops was also well known as a breeder of cattle and horses on his ranch. At the age of 70 he moved to Sidney, near Victoria, Vancouver Island, where he was also coroner and in charge of Red Indian Reserves, and indulged his taste for yachting and fishing. He was for many years a member of the British Medical Association, and his son, Dr. A. L. Hoops, C.B.E., of Malacca, late Principal Civil Medical Officer for the Straits Settlements, has attended a number of Annual Meetings of the Association.

The death is announced of FÉLIX MESSIL of the Pasteur Institute in Paris. Holding no medical qualification, he contributed much to the knowledge of medicine by his studies as a biologist. He was born in 1868, and became attached to the Pasteur Institute in 1892. He worked under Metchnikoff and Laveran on the protozoa pathogenic to man, and he collaborated with Laveran in the publication of *Trypanosomes et Trypanosomiasis*. It is claimed for Messil that he inaugurated the chemotherapy of diseases of parasitic origin. At the Pasteur Institute he organized classes in protozoal pathology for colonial doctors. He was a member of the Académie des Sciences, Académie de Médecine, and Académie des Sciences Coloniales, and Commander of the Legion of Honour.

The American ophthalmologist JAMES A. SPALDING, whose death at the age of 91 occurred at Portland, Maine, on February 27, had studied at Harvard under Oliver Wendell Holmes, had attended Brown-Séquard's lectures on internal secretions, and had seen Henry Jacob Bigelow perform the first litholapaxy in the world in 1878. Though deaf from youth, Dr. Spalding had learnt eleven languages.

Dr. LILLIAN WELSH, for thirty years professor of physiology and hygiene at Goucher College, Baltimore, Maryland, and one of the first American women to practise medicine, died on February 23, aged 80.

The following well-known foreign medical men have recently died: Dr. EVERT CORNELIS VAN LEERSUM, formerly professor of medicine at Leiden and director of the Netherlands Institute of Nutrition at Amsterdam; Professor WILHELM HEUCK, an eminent dermatologist of Munich, aged 62; and Dr. HERMANN SCHMIDT, formerly director of the Charité Hospital in Berlin.

Medical Notes in Parliament

Both Houses of Parliament this week discussed European affairs. The House of Commons also debated the Air Estimates and civil aviation policy. The Navy Estimates were down for March 17.

The House of Lords on March 10 gave third readings to the Blind Persons Bill and the Population (Statistics) Bill. Both measures had already passed the House of Commons, and the House of Lords has not amended them.

The Workmen's Compensation (Amendment) Bill, as amended in Standing Committee, was read a third time in the House of Commons on March 9. It was read a first time in the Lords on March 10.

The Divorce and Nullity of Marriage (Scotland) Bill was read a first time in the House of Commons on March 14.

Dr. Howitt has been added to the Scottish Standing Committee for discussion of the Registration of Stillbirths (Scotland) Bill. This measure was down for discussion on March 17.

Variation in Benefits of Approved Societies

Mr. JAMES GRIFFITHS asked on March 10 if the Minister of Health was aware of the growing concern felt by a number of the smaller approved societies operating under the National Health Insurance Acts at the loss of membership to larger and richer societies, who were able to offer inducements to insured persons to transfer because of the wider range of additional benefits offered. Mr. Griffiths asked the Minister to inquire into the possibilities of co-ordinating the health insurance services so that all those who made equal contributions should secure equal benefits under the State insurance scheme. Sir KINGSLEY WOOD said he did not agree that the smaller approved societies were ordinarily at any disadvantage compared with the larger societies as regards the additional benefits which they could provide for their members. Insured persons had freedom of choice of society, and some would seek to transfer from societies with relatively unfavourable valuation results to others in a more favourable position. There was, however, statutory provision for the protection of the weaker societies against undue loss of membership by transfer. The position, in his opinion, did not call for the course suggested by Mr. Griffiths, which would involve the abolition of the approved society system.

Health of Recruits

Introducing the Army Estimates on March 10, Mr. HORE-BELISHA said the labours of the scientists employed by the War Office would be co-ordinated by a Director of Scientific Research. Suitability and merit would in the Army, as in outside professions, determine the selection of officers for the most responsible posts. Mr. Hore-Belisha did not mention the Army Medical Corps, but said the general establishment of officers would be reduced by 1,000, and that warrant officers would be given an opportunity of discharging some of the responsibilities now confined to the commissioned ranks. The proportion of rejections was high among the 60,000 would-be recruits who tried to join the Army annually. The service should be enlarged whereby recruits below the normal physical standard could be brought into better health. Out of every hundred boys passed through the Physical Development Depot, which was now at Canterbury, ninety-two passed into the Army as fully fitted soldiers. At least one more such depot would be opened in 1938. Not only recruits in these depots, but all others who, in the opinion of the medical officer, needed special nourishment would have an extra issue of half a pint of milk. The issue would be "neat." The Government intended to adapt all barrack accommodation to the latest standard, and had arranged for experts to review the present arrangement for cooks, bearing in mind the importance

Dr. Helen Webb, and graduated M.B.Lond. in 1896 at the mature age of 44. Dr. White did not take up general practice. While still a student she felt strongly the urge to work for a change in the general attitude towards the mental needs of patients. This was many years before there was any question of psychology having a place in the medical curriculum. Dr. White was a foundation member of the Society for the Reform of the Lunacy Laws, and published notes and letters in the *British Medical Journal* and the *Lancet*. She never spared herself in working to help the helpless. Some of her colleagues had the pleasure of sharing her success in obtaining the discharge of patients detained in mental hospitals after showing evidence of cure. She gave freely of her time, energy, and means towards the establishment of homes for cases of early mental breakdown at its very beginning, before certification should be considered. The cause which she thus espoused has not yet come into the purview of the medical student, and she felt keen disappointment at failing to secure the co-operation of the profession. She had not let any of her many friends know of her illness, and in the presence of only a few near relatives she was buried in the Friends Meeting House ground at Wanstead.

Dr. THOMAS WILLIAM FRANCIS GANN, who died in London on February 24 at the age of 71, was well known as an adventurous explorer and an authority on the archaeology of Central America. The only son of William and Rose Gann of Hayling Island, he received his medical education at the Middlesex Hospital, qualifying L.S.A. in 1889 and obtaining the diplomas M.R.C.S., L.R.C.P. the next year. In 1907 he took the Liverpool D.T.M., and was for some time Principal Medical Officer in British Honduras and a member of the Legislative Council. His life interest in Central America began with a journey there in charge of a medical expedition to relieve the sufferers from an earthquake in Guatemala, for which he was thanked by the Colonial Secretary; after this he entered the service of the Government of British Honduras at Belize. He made frequent journeys of exploration into the interior in order to search for ruins of the ancient Maya civilization. Among his many publications on this subject were *Maya Cities* in 1927 and *History of the Maya*, which followed this book two years afterwards. When in 1930 Dr. Gann married Miss Mary Wheeler of Jersey their honeymoon took the form of a trip through the Guatemalan jungle. He believed that immigrants from North-Eastern Asia in the late neolithic period had first discovered America. Dr. Gann was elected a Fellow of the American Geographical Society in 1927, and was a Fellow of the Maya Society and a lecturer at Liverpool University on Central American archaeology.

Dr. JOHN PAUL ROUGHTON, J.P., who was formerly acting medical officer of health for Kettering and surgeon to Kettering General Hospital, died suddenly on February during a Mediterranean cruise. Dr. Roughton received his medical education at St. Bartholomew's Hospital, obtaining the diplomas M.R.C.S., L.R.C.P. in 1886 and the D.P.H. two years later. He held the post for some time of assistant electrician at St. Bartholomew's. The eighth son of the late Dr. J. J. Roughton, first chairman of the Kettering Local Board, he eventually succeeded his father in the Kettering practice which had been founded by his great-great-grandfather in 1710, and was one of the surgeons to Kettering General Hospital from 1897 to 1926, when he was elected consulting surgeon. In 1911 he joined the British Medical Association, and was a representative on the Representative Body at the Annual Meeting of the Association at Aberdeen in 1914. In 1933 he retired from practice and went to live in Cambridge with his only surviving son, Dr. F. J. Roughton, thus ending a family succession of medical practitioners in Kettering which had continued unbroken for more

than two hundred years. His wife died in 1931; they had both been prominent in local medical and social organizations.

The death took place at his home in Edinburgh of Dr. J. OLIVER HAMILTON, at the age of 52, from the result of his war disability. He was educated at George Watson's College. He graduated M.B., Ch.B. in 1908 at Edinburgh University, and took his D.P.H. in 1928. In 1910 he joined the R.A.M.C. Reserve of Officers and saw service as a regimental medical officer during the early hardships of the retreat from Mons to the Marne. He was attached in 1915 to No. 10 General Hospital, B.E.F., Rouen, and when he retired from the service in 1917 he was in command of No. 4 Ambulance Train, B.E.F., France. He was the son of a well-known and beloved Border practitioner, John Rodger Hamilton, M.D., of Hawick, who was chairman of the Scottish Committee of the British Medical Association when hostilities broke out in 1914, and did much valuable service in helping to muster the medical services in Scotland. Oliver Hamilton was associated in practice with his father, and after his death continued the practice in Hawick, where he held many public appointments, medically and socially. He was a football enthusiast, and was president of the Hawick Rugby Association in 1914. He was much esteemed by his patients for his gifts of heart and mind and outstanding professional ability. In 1919 he was forced to seek a warmer and more congenial climate in the South of England. He was actively engaged doing bacteriological research in Bournemouth and district. After leaving there he took a public health appointment in Barbados, B.W.I., and on relinquishing it was appointed chief medical officer to the Burma Corporation Limited. During the past five years he travelled extensively in the Dominions and elsewhere in a quest for renewed health. He will long be remembered by those who knew him for his gay courage and dauntless endeavour to carry on in the face of continued ill-health. He was an agreeable colleague, and possessed a charm of manner that came from a wide culture and a charitable judgment of his fellow men.

Dr. RICHARD LIDDON MEADE-KING of Taunton died suddenly on February 25 in the home of a sick friend whom he was visiting. He was born in 1861, and studied medicine at St. Bartholomew's Hospital, taking the M.R.C.S. and L.R.C.P. in 1892, the M.B., B.S. of Durham University in 1893, and the M.D. in 1895. Dr. Meade-King was honorary physician to the Taunton and Somerset Hospital from 1897 to 1924, when he was elected consulting physician, and was president of the hospital in 1931. He had been honorary secretary of the Somerset Archaeological Society, and was particularly interested in ornithology. He joined the British Medical Association in 1894, and was president of the West Somerset Branch in 1906-7.

Dr. JAMES ARTHUR RICHARD LEE of Mexborough, who died on March 2 aged 66, had practised in that town for twenty-seven years, and was recently chairman of the Doncaster Division of the British Medical Association. He began his career as a pharmacist, and then studied medicine at Sheffield University, obtaining the M.R.C.S. and L.R.C.P. diplomas in 1910. Dr. Lee took a prominent part in local affairs, and had been a Justice of the Peace since 1928. He was honorary surgeon to the Montagu Hospital, Mexborough, and as secretary of the medical staff of that institution played a leading part in the recent dispute with the board of management. His three sons are all members of the medical profession.

Mr. ARCHIBALD WILLIAM CUFF, F.R.C.S., one of Sheffield's best-known surgeons, died on March 9, after a long illness, at the age of 69. A native of Staffordshire, he studied medicine at Cambridge and St. Thomas's Hospital, taking the English Conjoint diplomas in 1893, the

Accommodation for the Sick on Troop Transports—On March 15 Mr. DE LA BIRE asked the Secretary of State for War, in connexion with the improved accommodation on transports for trooping, what steps were being taken to provide improved accommodation for the sick. Mr. HORE-BELLISHA said that the hospital accommodation in a transport provided both for invalids from stations abroad and for cases of sickness arising on the voyage. In the newer transports and the two under construction the cubic space for each individual had been increased. Improved types of bed and cot and better ventilation and lighting arrangements had been installed. The dispensaries were larger, and facilities for microscopic work had been provided. Several other kinds of improvement had been adopted, such as refrigerators instead of ice chests, proper cot-lifting units, and so on. The women's wards were similarly improved, and a separate medical inspection room for women had been provided. In the older transports higher standards of comfort and equipment had been provided as far as the accommodation would allow.

Universities and Colleges

UNIVERSITY OF OXFORD

Wilton Ernest Henley, B.M., second assistant in the Medical Unit at St. Mary's Hospital, formerly Rhodes Scholar of New College, has been elected to a travelling Fellowship on the Foundation of Dr. John Radcliffe at University College.

UNIVERSITY OF CAMBRIDGE

At a congregation held on March 11 the following medical degrees were conferred:

M.D.—S. McDonald, K. M. A. Perry, J. Smart, V. H. Riddell.
M.Chir.—W. F. Nicholson.
M.B., B.Chir.—A. L. Cochrane, *G. R. Rawlings, *J. K. Moore, R. L. Townsend, D. Rubin.

* By proxy.

During February the title of the degree of M.B. was conferred by diploma on B. J. Travers of Newnham College.

UNIVERSITY OF LONDON

Dr. Phyllis Margaret Kerridge has been appointed a teacher of physiology at University College in the Faculty of Science.

The date of the M.D. (Branch V) examination for internal and external students has been changed to the first Monday in July, for examinations in and after July, 1938.

Lord Horder has been appointed representative of the University at the International Congress on Rheumatism and Hydrology, to be held at Oxford from March 26 to 31, and Mr. P. H. Mitchiner a member of the University Extension and Tutorial Classes Council for the remainder of the year 1937-8.

Dr. J. A. Drake has resigned the post of teacher of dermatology at King's College Hospital Medical School.

I. P. J. MacNaughton, M.B., F.R.C.S., has been awarded a grant of £120 to enable him to study the methods of Dr. W. J. McNally of Montreal for not less than three months during 1938.

Revision of Building Plans

Changes have been decided upon in the plans for the University buildings to be erected to the north of the existing new buildings in Bloomsbury. Under the revised plan the view of the great Tower as seen from the north will be preserved, and Torrington Square will become the University garden. The original layout made provision for one continuous group of buildings covering the centre of the site from north to south and embracing a number of separate institutions each with its own internal organization. The architectural scheme consisted of a central spine from north to south, with cross-ribs from east to west, these ribs being joined by a continuous façade fronting on Malet Street. The plan included a number of enclosed courtyards, but it was found later that the requirements were more agreeably met by enclosing alternate courts only. The main units of the first section of the new building, comprising the Senate House, the University Library and Tower and the Institute of Education, School of Slavonic Studies, and Institute of Historical Research, balance each

other effectively. It has been decided to arrange future units of the University group round Torrington Square. The first buildings to be erected under the revised plan will be Birkbeck College and the School of Oriental Studies, occupying the southern end of the space available for building on the east and west sides of Torrington Square. The modifications in the architectural scheme are being submitted to the London County Council, the Holborn Borough Council, and other interested bodies.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A meeting of the Council of the College was held on March 10, with the president, Sir Cuthbert Wallace, Bt., in the chair.

Diplomas

A Diploma of Membership was granted to Robert Cox of Westminster Hospital.

Diplomas of Fellowship were granted to the following candidates:

I. E. Zieve, J. A. Dhacka, D. M. Jones, J. H. Mayer, R. G. Talwalkar, E. Vernon, Margaret M. Ferguson, R. H. Karmarker, M. N. Khanna, T. D. V. Krishnan, R. S. Lawson, J. F. Shepherd, M. Sofer Schreiber, S. P. Srivastava.

Diplomas in Ophthalmic Medicine and Surgery were granted, jointly with the Royal College of Physicians, to the following candidates:

G. H. Appel, A. H. Booth, D. K. Bose, G. H. Buck, E. W. B. Griffiths, S. P. Gupta, A. G. Hiremath, J. Jeels, J. B. S. Karki, H. O. Little, J. Macaskill, N. C. Mandalia, J. D. Martin-Jones, T. R. Pahwa, J. B. Patrick, H. Penman, C. V. D. Rose, E. N. Rosen, R. Stuart, R. A. Syed, S. Wigoder.

Mr. C. P. G. Wakeley was re-elected a Member of the Court of Examiners.

The University of Hyderabad was recognized for the study of anatomy and physiology for the Primary Fellowship examination.

Mr. P. B. Ashcroft, F.R.C.S., was re-elected Streatfeild Research Scholar.

A vote of condolence was passed on the death of Sir Raymond Crawford, registrar of the Royal College of Physicians of London.

INTER-COLLEGIATE SCHOLARSHIPS BOARD

The London Inter-Collegiate Scholarships Board announces that an examination for twelve medical scholarships and exhibitions of an aggregate total value of £1,443 will commence on May 9. They are tenable at University College and University College Hospital Medical School, King's College and King's College Hospital Medical School, the London (Royal Free Hospital) School of Medicine for Women, the London Hospital Medical College, and St. George's Hospital Medical School. Full particulars and entry forms may be obtained from the secretary of the Board, Mr. S. C. Ranner, M.A., at King's College Hospital Medical School, Denmark Hill, S.E.5.

The Services

HONORARY SURGEON TO THE VICEROY

Colonel A. F. Babonau, C.I.E., O.B.E., I.M.S., has been appointed Honorary Surgeon to the Viceroy and Governor-General of India, vice Colonel S. G. S. Houghton, C.I.E., O.B.E., I.M.S.

DEATHS IN THE SERVICES

Captain HORACE HARVARD KIDDLE, who had served in both the Indian Medical Service and the Royal Army Medical Corps, died in London on March 4, aged 60. He was born on October 30, 1877, was educated at St. Thomas's Hospital, and took the M.R.C.S., L.R.C.P. in 1902. He entered the Indian Medical Service as lieutenant on September 1, 1902, became captain after three years' service, and on December 18, 1907, exchanged into the Royal Army Medical Corps, changing places with the late Lieutenant-Colonel (then Captain) W. H. Odium, I.M.S. He was placed on temporary half-pay, on account of ill-health, on September 1, 1911, and retired on June 25, 1913. Since his retirement he had been in practice in London. While in the Indian Medical Service he held the post of chemical examiner and bacteriologist to the Government of Burma.

of food in health. The ration of butter would be issued at stations abroad as well as at home. Men discharged as unfit on medical grounds would be given twenty-eight days' furlough on full pay.

After debate the necessary Votes for the Army were carried through committee.

Diseases in Cattle

On a Supplementary Vote for the Ministry of Agriculture and Fisheries, which was agreed to on March 9, Mr. H. RAMSBOTHAM said that because of outbreaks of foot-and-mouth disease additional expenditure was needed in connexion with the Diseases of Animals Account. There had been a saving in respect of tuberculosis in cattle. During the first six months of 1937-8 there had been only seventeen outbreaks of foot-and-mouth, costing £35,000, but since then 267 other outbreaks costing £455,000. The outbreak which began in the middle of October was of a severe character. Its source was Central Europe. It was apparently reintroduced into France from North Africa. At the peak stage, when Great Britain had eighty-seven outbreaks, there were 45,085 in France, 22,419 in Belgium, and 21,604 in Germany. Since then in this and other countries there had been a satisfactory decrease. In January Great Britain had seventy-five outbreaks, in February twenty-six, and in March up to the 8th, one. The heaviest infection was at the time of the autumn mass migration of birds to the eastern and southern counties. It was highly probable that the birds were mechanical carriers of the virus. This country, by expenditure of £500,000 and destruction of 50,000 animals, had been saved a disaster. The Foot-and-Mouth Disease Research Committee had recently been strengthened. It consisted of scientists in the medical and veterinary professions under the chairmanship of Sir Joseph Arkwright. It was attending to the problem of immunization, which was complicated because there were several types of virus in this disease. Immunity might be secured against one type which would not give immunity against another. The committee had outlined experiments to see whether birds were susceptible to the disease or capable of mechanically transmitting the virus. The question of a serum, as employed in Germany, had been studied, but experiments had not been very successful.

SIR STAFFORD CRIPPS asked why less had been spent in dealing with tuberculosis in cattle, although the House was anxious that the purification of the milk supply should proceed rapidly.

Mr. W. S. MORRISON said the Foot-and-Mouth Disease Research Committee was ready to consider any suggestion. There was a complete international exchange of information on research, which was collected by a central office in Paris. He agreed that the policy of clearing the herds of disease was the most satisfactory way of securing a supply of clean milk. There was no slackening of efforts on that score, and the assault on the disease by a central State veterinary service would begin on April 1. About fifteen months ago a serum against foot-and-mouth disease had been received from Germany which was efficient in the mild attacks but could not be recommended as an alternative to slaughter. It was largely employed on the Continent in the recent outbreak, but the disease was completely victorious over the supposed immunity.

The Supplementary Estimate was approved.

Problems of Ventilation on the London Underground

In the House of Commons, on March 8, Sir RALPH GLYN moved the second reading of the London Passenger Transport Board Bill. He said that owing to the increased number of coaches attached to the ordinary trains run on the London Passenger Transport Board system and to the fact that the tunnels had been extended in many cases the ventilation had become of great importance. It was the duty of the Board to see that there was adequate and proper ventilation throughout the tube system. If the Bill was not given a second reading that work would be delayed. It had been found in practice that the ordinary extractor fans did not accomplish the work as satisfactorily as was expected, and

it was essential to acquire property and sink shafts in order to have clear ventilation to the upper air.

Last May there was presented to the House a report which was the result of an inquiry into the whole question of the factors that governed the omnibus stoppage of last year. At that inquiry a good deal of emphasis was laid on the fatigue and undue strain that the men suffered. It was essential, if the Board was to do their duty by its employees, that they should give effect to the recommendations in the report with regard to the provision of facilities for meals for their employees. The Bill carried out those recommendations.

After a long discussion, in which a motion was made for the rejection of the Bill, the debate was adjourned by 186 votes to 131.

Diabetes and Entry into the Civil Service.—Colonel COLVILLE states that there is no regulation debaring those suffering from diabetes from entry to the civil service. The existence of the disease is, however, a factor which has to be considered in the medical examination which is undergone by candidates for entry to or establishment in the public service. Each case is decided on its merits by the appropriate authority in the light of the medical report. Since it has to be considered not only whether the candidate is at present fit for the duties of the post he seeks but also whether he will remain so till the age of retirement, this decision must often be adverse in spite of the efficacious treatment available.

Osteopathic Research.—Mr. GROVES asked whether the Scottish Osteopathic Research Institute was licensed to perform vivisections, and where the experiments on rats were performed that were referred to in the first report of that Institute. Sir SAMUEL HOARE replied, on March 8, that the Scottish Osteopathic Research Institute was not a registered place under the Cruelty to Animals Act, 1876. The experiments in question were performed at the Institute of Animal Genetics, a registered department of the University of Edinburgh.

Marriage Allowances to Officers of the Navy.—On March 14 Mr. SHAKESPEARE informed Sir M. Sueter that the award of marriage allowance to officers of the Royal Navy and Royal Marines had been approved. A more detailed announcement must await the Navy Estimates later in the week.

Cod-liver Oil Imports.—Captain WALLACE, replying to Mr. R. Gibson on March 14, said that the total imports into the United Kingdom of cod-liver oil consigned from Norway amounted to 1,894 tons during 1929 and to 383 tons during 1937. Since the duty of 1s. 4d. a gallon was imposed on foreign cod-liver oil under the Ottawa Agreements Act, 1932, imports from Newfoundland had increased, and there had been a substantial development of United Kingdom production.

Grants for Veterinary Research.—On March 15 Mr. LLOYD informed Mr. Anstruther Gray that the Racecourse Betting Control Board had made a grant of £1,000 for investigation into grass sickness at the Institute of the Animal Diseases Research Association at Moredun, near Edinburgh, and a further grant of £750 had been approved. A grant of £625 had been made to research into disabling diseases of horses at the Royal (Dick) Veterinary College, Edinburgh, and a further grant of £650 had been approved. A grant of £500 had been made to the building fund of the Royal (Dick) Veterinary College and a further grant of £500 had been approved. It was proposed to make a grant of £500 to the Glasgow Veterinary College.

Dispensing of Insurance Prescriptions in West Lothian.—Mr. ELLIOT, replying to Mr. Mathers on March 15, said that the West Lothian Insurance Committee had recently decided that it was no longer necessary to require an insurance practitioner to dispense medicines for his insured patients in the Livingston Station area, West Lothian. As by statute it was open to any insured person affected by this decision to refer it for determination to the Department of Health for Scotland, it would not be proper for him to make any statement on the subject at present.

EPIDEMIOLOGICAL NOTES

Incidence of Principal Infectious Diseases in England and Wales during February

In the four weeks ending February 26, 1938, there were notified in England and Wales: 9,471 (121 per cent.) cases of scarlet fever; 6,749 (132 per cent.) of diphtheria; 4,559 (63 per cent.) of primary pneumonia; 12 (108 per cent.) of enteric fever. The figures in parentheses denote the increase or decrease per cent. of the expected numbers, deduced from the median values of the corresponding weeks of the years 1929-37. It is seen that with the exception of pneumonia there has been an appreciable increase of the principal infectious diseases in England and Wales during February, compared with that of the last nine years; this increase, with the emergence of measles in epidemic form in many areas, has severely taxed the hospital accommodation of many sanitary authorities.

Diphtheria and Scarlet Fever

In England and Wales notifications of diphtheria were 1,556, compared with 1,565 last week, while in London, Scotland, Eire, and Northern Ireland appreciable increases were recorded. There was an increase of deaths in England and Wales, 50 (34): in London, 8 (3); in Scotland, 7 (5); while in Eire deaths were the same as last week. 4. The figures in parentheses denote the deaths for the previous week. In England and Wales the notifications of scarlet fever have dropped from 2,429 to 2,367, the London figures being 198 and 182 respectively. On the other hand, increases were observed in Scotland 472 (459), in Eire 111 (90), Northern Ireland 97 (87). In England and Wales there were 8 (2) deaths, in Scotland there was 1 (1) death, and in Northern Ireland 1 (0). The figures in parentheses denote deaths in the previous week.

Measles

In the 125 Great Towns there were 44 deaths from measles, compared with 50 in the previous week: of these, 14 (13) occurred in London, 4 (3) in Birkenhead, 1 (2) in Manchester, 3 (1) in Liverpool. In London the epidemic appears to be increasing in magnitude; 2,165 cases of measles were reported in the L.C.C. elementary schools, compared with 1,801 in the previous week: the average daily admissions to the L.C.C. fever hospitals were 86, compared with 68 in the previous week; and the number of cases of measles under treatment on Friday, March 4, in the L.C.C. fever hospitals was 1,542, compared with 1,361 on the previous Friday. On the same day there were in these hospitals 1,277 cases of diphtheria, 819 of scarlet fever, and 277 of whooping-cough. The notifications of measles in London boroughs for the week under review are: Battersea 187, Bermondsey 45, Finsbury 25, Fulham 110, Greenwich 74, Lambeth 353, Shoreditch 16, Southwark 137, Stepney, 37. In Scotland 1,747 cases were notified, compared with 1,653 in the previous week, the figures for Glasgow being 1,247 (16), Edinburgh 66 (3), Paisley 94, Dundee 162, Aberdeen 48. The figures in parentheses denote the deaths. In Northern Ireland there were 237 cases, compared with 295 in the previous week: the figures for Belfast were 217 against 281, while the deaths were 12, compared with 17 in the previous week. During the week one death from measles was recorded in Dublin.

Infantile Paralysis

The epidemic of infantile paralysis in Victoria, Australia, which has lasted for eight months and which has been five times greater than any former outbreak, is now regarded as over, although sporadic cases may be expected for some time. During this period 1,984 cases were notified and there were 99 deaths (case mortality just under 5 per cent.).

Typhus in Morocco

In Morocco during the week ended February 26 298 cases of typhus were notified, of which 68 were in Marrakesh and 17 in Casablanca. During the same week there were 60 cases in Egypt, of which 5 occurred in frontier districts, 1 in Alexandria, and the rest widely scattered in the different provinces. In Tunisia there were 59 cases, of which 2 occurred at Bizerta and 1 at Tunis. In the previous week 24 cases were reported in Algeria, of which 5 were in Algiers and 2 in Oran. In the week ended February 5 20 cases were reported in the United States: South Carolina 1, Georgia 6, Florida 6, Alabama 3, Texas 4.

Medical News

The Trueman Wood Memorial Lecture will be delivered by Lord Horder before the Royal Society of Arts, John Street, Adelphi, W.C., on Wednesday, March 23, at 8.30 p.m. His subject is "Public Health: The Hygiene of a Quiet Mind." Applications for tickets should be made to the secretary of the society.

Count Castellani will read a paper on "Hygienic Measures and Hospital Organization of the Italian Expeditionary Forces during the Ethiopian War, 1935-6" before the Royal Society of Arts, John Street, Adelphi, W.C., on Wednesday, March 30, at 8.15 p.m. The chair will be taken by Sir Humphry Rolleston. Applications for tickets should be made to the secretary of the society.

A meeting of the Association of Industrial Medical Officers will be held at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., on Friday, March 25. At 5 p.m. there will be a business meeting, and at 6 p.m. Dr. J. C. Bridge will speak on "First Aid in Factories" and Mr. P. H. Michener on "Minor Surgery applied to Industrial Medical Services." On Saturday, March 26, at 10 a.m., at St. Thomas's Hospital, Mr. Mitchiner will give a practical demonstration of minor surgery and casualty surgical methods.

Ulaws (University of London Animal Welfare Society) has arranged a meeting for Tuesday, March 22, at 5.15 p.m., in the Beveridge Hall, Montague Place, W.C., for a discussion on the survey and regulation of British fauna, entitled "Man's Relation to Nature and his Response." The principal speakers are Lord Tavistock and Professor F. A. E. Crew. The regulation of economically or aesthetically beneficial or harmful species, field sports, epizootics, importation, and commercial exploitation will be examined in conjunction, and with reference to humane requirements. Applications for tickets should be made to the honorary secretary, Ulaws, 42, Torrington Square, W.C.1.

During the present week-end the Incorporated Society of Chiropractors is holding its annual convention in London at the Langham Hotel. To-day, Friday, March 18, at 5 p.m., Professor J. H. Burn, M.D., gives a lecture on "The Disinfection of the Skin and of Superficial Wounds," and on Saturday medical films will be shown by Mr. H. A. T. Fairbank, Sir Harold Gillies, Mr. R. Watson Jones, and Dr. Erwin Straus of Berlin. The guests at the annual dinner include Sir Cuthbert Wallace, President of the Royal College of Surgeons, Sir Charles Gordon-Watson, and Dr. T. Carnwath of the Ministry of Health.

A meeting of the Medical Section of the British Psychological Society will be held at the Royal Society of Medicine, 1, Wimpole Street, W., on Wednesday, March 23, at 8.30 p.m., when a paper will be read by Dr. Margaret Lowenfeld on "The World Pictures of Children: A Method of Recording and Studying Them."

A meeting of the Medico-Legal Society will be held at 26, Portland Place, W., on Thursday, March 24, at 8.30 p.m., when a paper will be read by Dr. S. W. Fisher on "Medico-legal Aspects of Coal Mining."

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended March 5, 1938.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for : (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for : (a) The 125 great towns (i) in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns (ii) in Northern Ireland.

A dash — denotes no cases ; a blank space denotes disease not notifiable or no return available.

Disease	1938					1937 (Corresponding Week)					1929-37 (Median Value Corresponding Weeks)

(ii) 9 " " " "

* 217 cases in Belfast alone.

† After October 1, 1937, puerperal fever was made notifiable only in the Administrative County of London.

Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

217 Recent Pulmonary Cavitation Treated Conservatively

S. COLD (*Hospitalstidende*, December 28, 1937, p. 1357) has investigated the after-histories of forty-eight patients who had been given conservative treatment for early cavitation of the lungs and who had been under observation for seven years or more. In every case the disease was of quite recent origin when this treatment was first instituted, and the diagnosis of cavities depended on a combination of clinical and radiological examinations. After seven years twenty of the forty-eight were dead and four had been obliged to undergo collapse treatment because the disease had progressed. After the seven-year interval five others had either died or relapsed. Thus there remained good results in nineteen, most of these ex-patients having become fully fit for work. The prognosis did not seem to be affected by the cavitation being left-sided or right-sided, nor by its position within a lung, but it seemed to be worse for the patients with known sources of infection than for others, presumably because the infection had been more massive in the former. There was a slight difference in favour of the patients treated with sanocrysin. Among the nineteen patients in whose sputa tubercle bacilli were not demonstrable on the completion of treatment there were as many as fifteen results counted as good, whereas among the twenty-six patients whose sputa still contained bacilli after more than a year there were only two results ultimately considered good. All the cases in which fever had lasted for more than two months did badly. The sedimentation test proved of little value to such a long-range prognosis. In another series of twenty-nine cases in which the cavitation was chronic between 75 and 80 per cent. of the ultimate results were bad, presumably because the comparatively stiff walls of the cavities had hindered healing. The author does not present his study of recent cavitation as an argument in favour of conservative treatment in preference to operative treatment, but he commends his findings as a corrective to the opinions of those who may be tempted to give the credit for every recovery to the special treatment they have employed.

218 Detection of Vitamin B₁ Deficiency

G. ALSTED and V. LUNN (*Ugeskr. Laeg.*, December 23, 1937, p. 1382) have minutely investigated dietetic records in Professor Meulengracht's hospital in Copenhagen with a view to discovering masked forms of vitamin B₁ deficiency among hospital patients. Well-defined vitamin B₁ deficiency seems to be comparatively rare in Denmark, and it has therefore been concluded that the customary diet of that country was adequate in this respect. Doubts have arisen on this score since it was shown that the requirement of vitamin B₁ is not uniform but dependent on, and rising considerably with, the calorie requirements. As there is at present a marked and growing tendency to raise the calorie consumption with foods containing no vitamin B₁, the suspicion arises that vitamin B₁ insufficiency may ensue. The authors have pursued this hypothesis in connexion with alcoholic patients, who are notoriously subject to polyneuritis, which is conceivably due to vitamin B₁ deficiency rather than to the direct toxic action of alcohol on the nervous system. They record in detail three cases of "alcoholic" polyneuritis and they employ a special form of registration of dietetic histories. With the help of Cowgill's formula they show that in spite of heavy alcohol consumption for several years no polyneuritis developed so long as the intake of vitamin B₁ was adequate. But shortly after drastic dietetic restrictions were enforced and the supply of vitamin B₁ thereby became defective, polyneuritis developed. The

cardiac insufficiency observed in one of these cases was probably also an evidence of vitamin B₁ deficiency. As in these cases the signs of polyneuritis appeared after years of abuse of alcohol and at a time when there was no great increase in its consumption, the authors identify them with vitamin B₁ deficiency rather than with any direct toxic action by the alcohol.

Reinfection with Syphilis

E. BISE (*Rev. méd. Suisse rom.*, December 25, 1937, p. 904) states that the occasional occurrence of reinfection with syphilis, although formerly denied, must now be admitted. According to the literature this happens in 0.16 to 0.28 per cent. of cases. Bise reports an instance which fulfilled most of the requirements that have been laid down for proof of reinfection. Both sores were diagnosed by the same observer and yielded spirochaetes. The first infection was incontestable, because the patient person who had caused at the same time in the patient and four friends similar balanopreputial lesions was traced, and was found to have secondary manifestations of syphilis. The treatment was bismuth in oil, neosalvarsan and 25 c.c.m. of bismuth in oil. The second sore appeared two and a half years later, in a different site—namely, the glans—after twenty-eight months' absence of clinical and serological signs. The incubation period and the signs generally were typical. Two requirements only remained unfulfilled: the source of the second infection could not be traced, and it was not deemed right to await the confirmatory appearance of a secondary rash.

Paroxysmal Tachycardia

A. MCG. HARVEY (*Ann. intern. Med.*, July, 1937, p. 57) has investigated five cases of paroxysmal tachycardia electrocardiographically, using an oesophageal lead. The pharynx was first anaesthetized, and the electrode then passed down the oesophagus until it lay behind the auricles, its exact position being determined either by measurement of the lead or by screening under x rays. The electrocardiograms thus obtained are compared with those procured with the usual leads. It is shown that by this technique the auricular complex is more easily recognized during an attack of tachycardia. The P-waves appear much more prominent, and the true nature of the arrhythmia is more readily recognized. Three of the cases under review were shown to be of supraventricular origin, one of ventricular origin, and one was undetermined. In one of the cases in which the tachycardia was of supraventricular type the patient was taught to arrest an attack by light pressure over the right carotid sinus; in a second case the attack could be curtailed by pressure on the eyeballs.

Hyperinsulinism

E. ZISKIND and W. BAYLEY (*J. Lab. clin. Med.*, December, 1937, p. 231) report a case of hyperinsulinism due to adenomata of the pancreas. The patient, a woman aged 38, developed a condition of marked restlessness amounting at times to a state resembling acute mania. She had had numerous similar attacks within the previous five years. After the attacks she usually became comatose, and it was ultimately discovered that she could be roused from the coma by the intravenous injection of glucose solution. Blood-sugar tests were then made, and it was found that the attacks were due to hypoglycaemia: her fasting blood sugar was in the region of 44 mg. per 100 c.c.m. Her abdomen was opened and the pancreas explored, but no tumour was felt, and the abdomen was closed without resection of the pancreas. As the attacks continued the abdomen was explored again and two-thirds of the pancreas and the spleen were removed. The resected portion of the pancreas contained two adenomata

On the occasion of the fiftieth anniversary of its foundation the Obstetrical and Gynaecological Society of Vienna held a special meeting on February 16, when Dr. I. Fischer read a paper on the Society's activity during fifty years and Dr. O. Frankl a paper on Semmelweis.

Dr. Edith Summerskill has been adopted by the Labour Party as its candidate for Parliament in the by-election at West Fulham, caused by the death of Sir Cyril Cobb.

On Wednesday, March 30, Lord Horder will take the chair at an unusual luncheon, which is being given by the Children's Minimum Council. The menu will be based on the diet recommended by the B.M.A. Nutrition Committee in 1933 as the minimum necessary for health and suitable for unemployed families. The Children's Minimum Council was founded soon after the report of the Nutrition Committee was published, and much of its propaganda has been centred upon it. It urges that the allowances for the unemployed should be at least sufficient to cover the food requirements of the B.M.A. scale, and has worked, with some success, for a more generous provision of free meals and milk for children and nursing and expectant mothers in all families where the expenditure available for food is below this scale. The luncheon, which is taking place at the London School of Economics, is intended to give medical men, Members of Parliament, and leading sociologists an opportunity of sampling the "minimum diet" for themselves. A limited number of invitations is being issued. Any doctors who would care to attend the lunch should apply as soon as possible to the Children's Minimum Council, 72, Horseferry Road, S.W.1.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, Ailology
Westcent, London.

SECRETARY, Medisecra Westcent, London.

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: Associate, Edinburgh; telephone: 24361 Edinburgh), and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: Bacillus, Dublin; telephone 62550 Dublin).

QUERIES AND ANSWERS

Urticaria

"C. DE G." writes: I would be thankful for advice as to the treatment of urticaria in a boy of 5. The usual causes have been inquired into and the usual remedies, dieting, drugs, change of clothing, etc., tried without avail. The condition has existed for about a year.

"Geographical Tongue"

"A. P." writes: Can any reader tell me the cause of geographical tongue and the most effective treatment? I have had several cases in the past two years, and found no lotion or mouth-wash of any avail. Apart from being somewhat alarming to the parents the disease seems to have no serious effect on the health of the child.

James Yearsley: An Inquiry

Mr. CECIL P. G. WAKELEY writes: I have read with interest the article in your issue of February 26 on "James Yearsley and the Metropolitan Ear, Nose and Throat Hospital," which I see is in its centenary year. The writer of this article refers to Yearsley as "the originator and proprietor (though not the editor) of the *Medical Circular*," which journal was amalgamated with the *Medical Press* in 1866 to form the present journal, the *Medical Press and Circular*, which will achieve its centenary in January, 1939. I should therefore be much interested to know on what the writer of the article bases the statement that Yearsley both owned and founded the *Medical Circular*. The first editor was George Ross, M.D., but no evidence has so far been discovered, I believe, as to the exact relationship, financial and otherwise, between Yearsley and Ross; in fact but little is known of the history of the *Medical Circular* in its early years and indeed throughout its existence. I would therefore be glad if you could publish this letter in case it may catch the eye of someone who could, for instance, put either me as editor or the present proprietors of the *Medical Press and Circular* in touch with the descendants of George Ross or James Yearsley. George Ross, by the way, was born at Stonehouse, in Devon, in 1815 and died as medical officer of health of St. Giles District, London, in 1875. The *Medical Circular* and *General Medical Advertiser* (to give it its full title), by the way, was not founded till January, 1852—that is, six years after the founding of the *Medical Directory*.

** We have referred this inquiry to our contributor R. S. S., who writes:

The *Dictionary of National Biography* article on James Yearsley (1900, 63, 311), which is signed by the familiar and usually accurate initials, "D.A. P.," states that Yearsley "was the originator and proprietor of the *Medical Circular* from 1852 until it was consolidated with the 'Dublin Medical Press' in January, 1866." J. F. Clarke (of the *Lancet*), who was a contemporary of Yearsley, says in his *Autobiographical Recollections of the Medical Profession* (London, 1874, 376): "Yearsley was part proprietor of a medical journal which at that time exerted some influence on the profession. In the conduct of this journal he was associated with a gentleman of great ability and one of the most brilliant writers of the day. [This refers to Dr. George Ross.] . . . That the *Medical Circular* did not attain the high position to which it was entitled from the ability and energy with which it was conducted was mainly due, I believe, to the really Quixotic character—or perhaps, to speak more correctly, the obstinate conduct—of Yearsley." James Yearsley has a number of descendants living; the most accessible member of his family is Mr. Macleod Yearsley, the aural surgeon, of London.

The "Emergency Bag"

The bandage mentioned in Dr. C. C. H. Chavasse's note (February 26, p. 496), when describing the contents of his emergency bag, is a "cellona" plaster bandage, manufactured by T. J. Smith and Nephew, Ltd.

LETTERS, NOTES, ETC.

Disclaimers

COUNT CASTELLANI OF KISYMAIO, K.C.M.G., M.D., F.R.C.P., writes: My attention has been called to certain articles published in various lay daily papers, after my recent return from America, some paragraphs of which might be interpreted as praising my private professional work. I wish to state that I strongly object to these notices and that I have had nothing to do with them or, as a matter of fact, any other notices that have appeared previously. I have never granted any interviews and the articles have been published absolutely without my knowledge.

Miss CONSTANCE OTTLEY, F.R.C.S., of Hove, wishes to state that the publicity given in the lay press to her article in the *Journal* of March 5 was without her knowledge or consent.

Corrigendum

In a leading article on the function of vitamin C which appeared in the *Journal* of March 12 at page 571 reference was made to "redoxon" as "Merck's ascorbic acid." Redoxon is a trade name for ascorbic acid as supplied by Roche Products Ltd.

226 Treatment of Delayed Union of Fractures and of Pseudarthrosis

M. BOPPE and J. FRESSAIS (*J. méd. Bordeaux*, December 18, 1937, p. 577) discuss the advisability of treating cases of delayed union and pseudarthrosis by means of multiple perforations of the bony ends, and give the results they have obtained in nine cases so treated. It has been found that perforation has a vasodilator action causing an intense local hyperaemia and the formation of callus. This method of treatment was tried experimentally on rabbits, and later in nine cases, which are fully described. The perforations were made according to the technique of Beck, by means of an electric drill—ten or twelve in each fragment of bone. In cases of superficial bones such as the tibia or radius operation may be carried out by the subcutaneous route under local anaesthesia, but for deep-seated bones complete exposure must be obtained in order to avoid the nerves and vessels. Immobilization is essential until complete consolidation has taken place. Treatment by this method is only successful when the fragments are almost in contact: in one instance, where the fragments were near but at an angle, osteotomy was performed after drilling. In cases of open fracture with chronic suppuration perforation is contraindicated until healing has occurred. In five cases drilling was carried out for delayed union, and in four instances for pseudarthrosis. In the first group union was achieved in six weeks to two months, and in the second group a successful result was obtained within three and a half months in all but one instance.

227 Conservative Treatment of Fractures

K. MERMINGAS (*Zbl. Chir.*, November 27, 1937, p. 2722) considers repeated radiographic examinations of a broken bone unnecessary, and at times even disturbing for the patient and relatives. The old criteria of healed fracture—namely, strong callus, restitution of the extremity in all directions, mobility of the joints, and good condition of the muscles—still hold good. The repeated radiographic controls of the fracture showing possibly some overlap of the fragments or lack of alignment only disturb the peace of mind of the physician, and of the patient and his relatives. This sometimes leads to a superfluous or even harmful attempt at reposition of the fracture, or even to unnecessary operative interference. The author therefore omits all radiographic control after the fracture has been diagnosed and properly reduced. He avoids all manipulation during the first ten to twelve days following the fracture, during which time the callus is being formed. He illustrates his point of view by a number of radiographs taken immediately after the fracture and some months or years afterwards. The advantages of his mode of treatment, in his view, are: (1) avoidance of surgical shock and of respiratory and cardiac complications; (2) shortening of the duration of the extension; (3) prevention of the danger of pseudarthrosis.

228 Regional Jejunitis

C. GOTTLIEB and S. ALPERT (*Amer. J. Roentgen.*, December, 1937, p. 881) report a case of regional jejunitis which presented the following syndrome: severe epigastric pain, vomiting, evidence of gastro-intestinal bleeding, fever, mild leucocytosis, absence of radiographic evidence of a gastric or duodenal lesion, and radiographic evidence of stasis and irregular defects in the upper part of the small intestine. At operation inflammatory changes were found without evidence of fibrosis or stenosis. The variable radiographic findings were due partly to deformity caused by the inflammatory changes, but more to the resulting disturbances of motility.

Therapeutics

229

Actinomycosis

E. NEUBER (*Wien. klin. Wschr.*, January 7 and 14, 1938, pp. 12 and 48) discusses the diagnosis and treatment of actinomycosis. He believes in the efficacy of gold together with specific vaccine therapy even in very severe cases where all other therapy has failed, provided the defensive forces of the patient are adequate. The treatment is of no avail in patients whose resistance is exhausted. Necropsy in such cases revealed severe extensive parenchymatous and amyloid degeneration of the vital organs, which explains why several of these patients were even made worse by the gold and vaccine treatment. The state of the patient's resistance can be determined by means of the specific intracutaneous allergic reaction evolved by the author in 1931. Patients with a negative reaction are at first submitted to gold therapy. Only when the reaction becomes positive are they fit for the specific vaccine therapy. Lately the author has been using gold therapy even in cases in which the specific allergic reaction was positive. This seemed to enhance the effect of the subsequent vaccine therapy. The initial dose of the vaccine depends on the intensity of the specific allergic reaction. It should correspond to the strength of the allergic reagent which still gives a positive reaction in the patient but gives no reaction in a healthy individual. A course of vaccine therapy usually consists of ten to fifteen injections given at intervals of five to seven days, the dose being gradually increased. Strong focal reactions should be avoided, as they may lead to death in cases where the actinomycosis affects a vital organ. Autogenous vaccines seem to give the best results, but when their production is not practicable a polyvalent vaccine is used. In cases in which the first course of gold and vaccine therapy has not brought about the desired result a second course may be given after eight to ten weeks. In six cases good results have been obtained from convalescent serum, but the opportunities of treating patients with such serum are obviously restricted.

230

Vasomotor Rhinitis

H. BJÖRCKMAN (*Nord. med. Tidskr.*, January 1, 1937, p. 12) discusses the comparative merits of tuberculin and some non-specific protein in the treatment of vasomotor rhinitis by gradual desensitization, and concludes that the former method is dangerous, as it may provoke a violent specific reaction. Between 1933 and 1936 the author has treated some sixty cases of vasomotor rhinitis with a vegetable protein. In fifty of these cases he has ascertained by a questionnaire the late results of his treatment: his patients' ages ranged from 15 to 60. Other allergic phenomena included asthma in thirteen cases, and urticaria, eczema, pruritus, Quincke's oedema, etc., in several others. The accessory nasal sinuses were diseased in eleven cases. The desensitization was effected by the subcutaneous injection of 0.05 to 0.1 c.cm. of the "novoprotein." The injections were given twice a week, and the doses cautiously increased, the highest dose being usually 1 c.cm. repeated a few times at intervals of a week. The initial dose for exceptionally sensitive patients suffering also from asthma was 0.01 c.cm., and in the course of ten injections this would be raised to 0.5 c.cm. When there was a specific reaction on the day after an injection the dose of the next injection was reduced, and in such hypersensitive cases the final dose was no more than 0.2 to 0.3 c.cm. One patient who became nearly symptom-free, and who has remained so for two years; could never tolerate more than 0.05 c.cm. in the course of sixteen injections. This and similar cases have convinced the author that, with patience, as good results can be achieved with the hypersensitive as with other cases. The analysis of his late results showed that permanent recovery or improvement could be claimed in thirty-two of the fifty cases.

each about 2 cm. in diameter. The patient died thirty-two hours after the operation. The pathologist's diagnosis was adenoma of the islets of Langerhans with probable low-grade malignancy. In a section of the pancreas (not through the tumour nodules) the majority of the islets were from two to four times the normal size. The importance of considering hypoglycaemia in the diagnosis of temporary cerebral disturbances is emphasized. An attempt was made in this case to discover how much glucose was required to maintain the blood sugar at a normal level. It was found that 155 mg. of glucose per kilogramme of body weight per hour were necessary to maintain the blood sugar at a level of 90 mg. per 100 c.cm. The injection of 20 units of insulin intravenously increased the amount of glucose required to a figure of 385 mg. per kilogramme of body weight per hour.

222 Acute Epidemic Myalgia

W. THIELE (*Dtsch. med. Wschr.*, January 1, 1938, p. 7) reports from Rostock a small outbreak of acute epidemic myalgia. The severity of the symptoms was in marked contrast to the speed with which they cleared up in response to treatment or, in some cases, without it. In every case the onset was sudden, and in this respect the disease presented the clinical picture of an acute infection caused by a "chill." Several groups of muscles were the seat of violent pain, and in every case the muscles of the shoulders, of the upper part of the back, and of the thorax were involved. The abdominal muscles were also involved in two patients. This sudden and most violent pain limited the movements of nearly all the patients to a greater or less degree. In two cases the respiration was obviously interfered with, the respiratory symptoms dominating the clinical picture. Indeed the respiration was so rapid and superficial in these cases that the appearance they presented seemed almost pathognomonic of some disease of the lungs or pleurae. Though no temperatures above 100.4° F. were recorded, it should be noted that none of the patients were admitted to hospital till several days after the onset of the symptoms. The accumulation of remarkably similar cases within a small area and in rapid succession was very suggestive of an infectious disease, yet the cases remained sporadic. Discussing the differential diagnosis, the author first mentions ordinary myalgia. A clinical and radiological examination should eliminate the diagnosis of some intrathoracic complaint even when the respiration is embarrassed. The involvement of the abdominal muscles may lead to the mistaken diagnosis of some abdominal condition.

Surgery

223 Cancer of Tongue, Lip, and Cheek

H. E. MARTIN (*Surg. Gynec. Obstet.*, December, 1937, p. 793) reviews the results of treatment as seen at the end of a five-year period in 672 cases of cancer of the tongue, lip, or cheek. The cases were consecutive and unselected. In the series there were 322 cases of cancer of the tongue, 251 of the lip, and 99 of the cheek. After having allowed for those patients who died from some other disease without recurrence or who were not traced it was seen that 215 in the first group, fifty-eight in the second group, and fifty-nine in the third had died from cancer. This left a total of seventy-four patients who were known to be well at the end of five years after treatment for cancer of the tongue—that is, 26 per cent.; 130 who had suffered from cancer of the lip alive and free from disease—69 per cent.; and twenty-eight (28 per cent.) were alive and well in the third group—cancer of the cheek. It was seen that cancer of the tongue increased in frequency with age, and nearly half the cases occurred in patients over 60. The proportion of five-year cures decreased with age from 39 per cent. in the group under

40 to 16 per cent. in the group over 60. Out of the total of 322 cases of cancer of the tongue no fewer than 276 were in males, with only 18 per cent. of five-year cures. The growth was most common in the middle third of the tongue, being found there in 180 cases. An epidermoid carcinoma, Grade 2, was the most frequent type of growth, and occurred in 177 instances. There were sixty-nine cases of associated leucoplakia, and seventy of associated syphilis. Treatment given consisted of radium, x rays, or surgery, either alone or in various combinations. It is suggested that some uniform method of reporting end-results in cancer should be adopted.

224 Monteggia's Lesion

A. DI PRAMPERO (*Chir. Organi Mov.*, December, 1937, p. 108) records his observations at the Rizzoli Institute of Bologna on eighteen cases of the lesion described by Monteggia in 1824—dislocation of the head of the radius associated with fracture of the ulna. Four patients were below the age of 10 years, nine between 10 and 30, and five over 30; seventeen were males and only one a female. In twelve the right arm was affected, and in six the left. The symptoms consisted of swelling of the forearm and elbow in all the recent cases, shortening of the forearm, and limitation of passive movements owing to pain, especially flexion beyond 90 degrees and supination. The following complications were observed: lesions of the skin in two cases, fracture of the shaft of the humerus in one case, of the condyle in one case, of the olecranon in one case, and a musculo-spiral paralysis which was complete in two cases and incomplete in two. Nine of the cases were treated by reduction under an anaesthetic, followed by immobilization of the limb for fifteen to twenty days, according to the patient's age, with physiotherapy, including massage and electrical treatment. In seven an operation was necessary, and in two no special treatment was undertaken.

225 Chronic Constrictive Pericarditis

C. LAUBRY and A. MALINSKY (*Arch. Mal. Cœur*, November, 1937, p. 841) discuss the aetiology, pathology, symptomatology, and treatment of chronic constrictive pericarditis, which is the cause of the characteristic clinical condition referred to as Pick's syndrome. The aetiology is obscure. There is no proof that rheumatism has any causal connexion, but tuberculosis may be responsible in a limited number of cases. Essentially the condition consists of a thickening and calcification of the pericardium, mainly affecting the site of entry of the venae cavae. The heart usually is not enlarged; in long-standing cases it is small and atrophied. The liver is congested. The ventricles do not fill to their full extent, as their capacity for expansion is diminished by the inextensible pericardium. The venous stasis affects mainly the systemic circulation. The pulmonary circulation is not greatly affected, so that dyspnoea is not a prominent symptom. The signs of stasis are: (1) ascites; (2) oedema of the legs; (3) distension of the veins of the thoraco-abdominal parietes and legs; (4) occasionally oedema and venous distension of the face and arms; (5) cyanosis. The association of marked cyanosis with the absence of orthopnoea is an important diagnostic point. Arterial tension is low and pulsus paradoxus may be present. Radiological examination is of value, and is usually decisive. The evolution of the disease is slow. Medical treatment is only of palliative value, but paracentesis of the abdomen and thorax, the administration of diuretics, and the restriction of salt are useful. The only curative treatment is Delorme's operation of resection of the pericardium: the operative mortality is about 25 per cent. In successful cases the results are excellent, and the patient is restored to normal health and activity. Two cases of the condition are fully reported in the article. Both patients refused operation.

syringes, mounted on a stand and connected by a three-way tap to an infusion cannula. The eunarcen syringe is fitted with a "drop-by-drop" device. By this means coramine may be given to prevent respiratory failure, and shocked or toxic cases may receive 5 per cent. glucose or saline, with circulatory stimulants, such as strophanthin. Experience with this method has been very satisfactory; electrocardiographic investigation of eighty-five cases has shown no serious abnormality, and there has been no evidence of liver damage or of disturbed carbohydrate metabolism. The maximum dose of eunarcen has been 25 c.cm.; aged, ill, or toxic patients require much less, and have stood severe and prolonged operations surprisingly well.

236 Intravenous Morphine

C. J. BETLACH (*Proc. Mayo Clin.*, November 17, 1937, p. 733) describes the intravenous administration of morphine sulphate, which has been extensively used at the Mayo Clinic as an adjunct to regional analgesia and in peroral endoscopy. The method may also be used in any case in which rapid action is desired—for example, as a pre-anaesthetic medication in emergencies. The amount used has varied from 1/24 to 1/4 grain: tablets of 1/6 or 1/4 grain may be dissolved in 1.5 or 2 c.cm. of sterile water, or ampoules of solution may be used. After about 1/24 grain is injected a pause of thirty seconds allows one to judge the response and to note possible idiosyncrasy. The injection is then slowly continued until the desired result is obtained. The advantages of the intravenous route are that the full effect is at once attained, while the dose may be accurately controlled. The duration of the effect, in spite of its rapidity, is about the same as when the morphine is given hypodermically.

237 Spinal Anaesthesia

L. MASSION (*Sculpel*, Liège, December 18, 1937, p. 1738) describes in detail Sebrecht's method, which he claims is undoubtedly the best for all operations below the diaphragm. For patients over 15 he uses Howard Jones's percaine solution, and he admits only two contraindications—namely, cerebrospinal disease and sepsis at the site of injection. Sedol is injected one hour before, and in cases of hypertension, particularly in the aged, or in severe hypotension, an intramuscular injection of ephedrine is given immediately before the anaesthetic. The puncture is made sitting, or lying with the affected side uppermost; the site should not be higher than the third or fourth lumbar space; 5 c.cm. of percaine are injected and the needle is left in place, with its stylet reinserted. For unilateral operations the patient remains lying on the sound side, for bilateral he is cautiously turned face down. For upper abdominal operations, which require skin anaesthesia up to the nipples, the table is kept level; for lower abdominal operations, in which analgesia should reach the epigastrium, it is tilted slightly head down. At five-minute intervals skin sensibility is tested, and a further 5 c.cm. of solution are injected until adequate anaesthesia is obtained. The operation may be begun thirty-five minutes after the first puncture. The amount of percaine employed varies from 5 to 110 c.cm. and averages 15 c.cm. for lower and 20 to 30 c.cm. for upper abdominal operations. It should be greatly reduced in pregnant women, who are unduly sensitive to it, and also in all toxic cases. During anaesthesia the pulse, respiration, and mental condition must be closely watched. Minor degrees of syncope occurring early are remedied by deep breathing, sponging the face, and reassuring the patient. In more serious difficulties ephedrine should be given intravenously and intramuscularly. Severe collapse must be treated promptly with intravenous or intracardiac adrenaline, artificial respiration with oxygen, cardiazol, and lobeline. If the anaesthesia is not quite adequate, a slow and careful

intravenous injection of sedol will calm and comfort the patient. If the failure is more complete a small dose of evipan or eunarcen will ensure a good result. The patient is kept horizontal for the first twenty-four hours, and after high abdominal operations the foot of the bed is raised for the first few hours. Sequelae, including headache, are now very rare. The latter may be treated with aspirin or belladonna, or 20 to 40 c.cm. of distilled water or 10 per cent. saline injected intravenously.

Obstetrics and Gynaecology

238 Uterine Sarcoma

T. DE SOUZA (*Ann. bras. Gynec.*, December, 1937, p. 544) reports three more cases of sarcoma of the uterus. He reported three cases in 1935, after which he saw no others for two years or more until the present series, all of which were seen within the last eight months. The first was that of a woman of 38 who was admitted for uterine haemorrhage after two months' amenorrhoea. This was diagnosed as due to an abortion, which diagnosis was confirmed after examination of the curettings. Bleeding persisted, however, in spite of treatment, and finally subtotal hysterectomy was performed. Histological examination of the uterus showed a round-celled sarcoma. The second case was that of a coloured woman of 34 who was admitted with an enormous solid tumour (larger than a twin pregnancy) of the abdomen. A laparotomy was performed in May, 1937, but it was impossible to remove the tumour. A small piece was taken for examination, and the provisional diagnosis of sarcoma was confirmed. An interesting point about this patient is that the tumour must have attained its enormous size in less than sixteen months, for a myoma of the left broad ligament had been removed at the end of January, 1936. After the second operation the sections of the first tumour were re-examined and the diagnosis of myoma verified, but a section was made of a part of the tumour which had not previously been examined, and this showed some characteristic sarcoma cells, thus establishing the presence of a sarcoma within a myoma, a condition which the author claims to have described for the first time. The third case was that of a woman of 28 with chronic appendicitis, retroversion of the uterus, and a cervical polyp. The polyp was removed by torsion, and on histological examination was found quite unexpectedly to be a round-celled sarcoma.

239 The Tension of the Fontanelles

H. BRAUN (*Zbl. Gynäk.*, January 1, 1938, p. 15) alludes to measurements of the tension in the anterior fontanelle made in healthy newborn infants by Rendelli and Nizza, using Schiotz's ocular tonometer. He describes a modified and more sensitive instrument, and records measurements made in infants suffering from intracranial birth injury. Allowance must be made for the increased tension due to crying or straining, and for the size of the fontanelle. For small fontanelles, under 18 mm. in diameter, the average tension in millimetres of water is 40 to 65; diameters of 18 to 20 mm. correspond to a tension of 50 to 65 mm. of water, and larger fontanelles give average readings of 70 to 90 mm. of water. Braun finds that little clinical value attends single measurements of pressure, but by taking repeated daily readings has found three main types of pressure curve. The normal curve, occurring after most spontaneous labours or easy interventions, is approximately horizontal. A curve showing pronounced ups-and-downs and lying above the normal values for the size of the fontanelle, was found after difficult spontaneous or operative labours in many cases, and, taken together with the history and the infant's behaviour, is believed to be often significant of multiple small intra-

Anaesthesia

231 Respiratory Failure During Ether Anaesthesia

J. BERGER and G. DELAHAYE (*Presse méd.*, December 15, 1937, p. 1795) discuss the nature and regulation of the respiratory rhythm during ether anaesthesia, and comment on the occurrence of various degrees of apnoea. This is seen most often in dehydrated, wasted, and cachectic types, in neuropathic persons, particularly women, and in those who have had preliminary medication with opiates, barbiturates, or both. The authors show the difficulty of estimating by tests the patient's response to pre-medication and the error of adopting an arbitrary routine dosage. They point out that the psychic factor is one of the most important, for it is not itself subject to tests, and it may render invalid the results of other investigations. Though in practice apnoea may be successfully treated with carbon dioxide, the use of the latter is not without dangers and drawbacks. The authors consider that the advantages of pre-medication have been exaggerated, as have the dangers of etherization. They suggest that atropine should be more widely used, both for its effect on the vagus and for preventing hypersecretion, though it has certain disadvantages—for example, accelerating the heart and increasing the resistance to anaesthetics.

232 Cyclopropane Anaesthesia

H. KILLIAN and K. KUHLMANN (*Zbl. Chir.*, December 11, 1937, p. 2817) report further upon cyclopropane anaesthesia, having anaesthetized a series of seventy cases with gas manufactured in Germany. Their opinion is very favourable, and their observations generally correspond with those of American and English workers. Apart from a few cases of cardiac irregularity, caused by excessive concentration of the gas and quickly remedied by increased oxygen, they have found no undesirable effects upon the circulation. The blood pressure is normal or slightly raised, the pulse slightly accelerated. There have been no complications or sequelae, except occasional slight vomiting. The manifest advantages of the gas are the rapid and comfortable induction and recovery, and the high percentage of oxygen which may be given with it. The authors feel that cyclopropane alone may not give adequate relaxation for abdominal surgery but that it is useful in combination with local anaesthesia. They have found it of value in the surgery of infants and young children, where ordinary methods may be difficult or dangerous. They have used a circuit breathing apparatus, with carbon dioxide absorption; the gas concentration is usually 15 to 20 per cent. They are confident that German chemists will soon produce the gas at a price low enough to allow of its general adoption.

233 Peridural Anaesthesia

E. KRAAS (*Schmerz Narkose-anaesth.*, December, 1937, p. 163) describes in detail the anatomy of the peridural space and the method of peridural anaesthesia. The space is enclosed by the two layers of dura mater, the outer of which is closely adherent to the wall of the spinal canal. The width of the space is greater dorsally than ventrally, and varies at different levels; it is narrow in the cervical region, wider from the second to the seventh dorsal vertebra, narrow again down to the tenth dorsal vertebra, and much expanded down to the second lumbar vertebra. It is filled with soft fat and connective tissue, in which lie the nerves, vessels, and ganglia. The venous plexuses lie chiefly ventrally and laterally; the middle line posteriorly is relatively free from vessels, and is therefore chosen for injection. There is no connexion between the epidural space, in which there is a negative pressure, and the subdural space, in which the pressure is positive. The utmost care must be taken to avoid pene-

trating the subdural space or injecting the solution into a vein. The injection is made in the middle line with a fine, short-bevelled spinal needle. When about 3 cm. deep the stylet is removed and a syringe filled with sterile saline connected. While the needle is cautiously pushed deeper, firm pressure is kept on the piston, which cannot move until the dura is pierced. The sudden release of pressure indicates that the point has entered the epidural space, while the issuing fluid protects the vessels from possible injury. The syringe is then detached to verify that no cerebrospinal fluid escapes, and a trial injection of 10 c.cm. of 1 per cent. novocain is made. If after ten minutes there is no lumbar anaesthesia it is certain the needle has not entered the subarachnoid space and the anaesthesia may be completed. Various solutions may be used—the author, for example, prefers a solution of 3:1,000 panto-cain; 0.1 c.cm. of ephetonin is given subcutaneously after injection. The anaesthesia is established in fifteen minutes and lasts usually for three hours. The area anaesthetized depends upon both the amount injected and the level of injection; the anaesthetic solution spreads equally upwards and downwards, therefore the injection is centred in the zone which it is desired to anaesthetize. The author uses from 15 to 20 c.cm. of the 3:1,000 panto-cain. For operations upon the lower limbs or perineum the injection is made between the first and second lumbar vertebrae, for lower abdominal operations between the tenth and eleventh dorsal vertebrae, and for upper abdominal operations between the eighth and ninth dorsal vertebrae. The advantages of the method are the absence of collapse, of any serious fall of blood pressure, and of headache, etc., while the cerebrospinal fluid is unaffected; also a sharply defined zone of analgesia is obtained. The chief drawbacks are the difficulty of the procedure and the long time required—namely, half an hour.

234 Evipan Anaesthesia

E. POULIQUEN (*Mém. Acad. Chir.*, 63, 30, 1217) writes with enthusiasm of anaesthesia with intravenous evipan sodium after a personal experience of 2,300 cases since 1933. He has used it mainly in single doses for brief or trivial operations, and also as a preliminary or supplement to other forms of anaesthesia, general or local. In about a hundred cases, including six of gastrectomy, he has obtained prolonged anaesthesia by repeated doses with satisfactory results, but this method is more complicated and requires skilled assistance. He considers that evipan is safe, but allowance must be made for individual susceptibility, particularly in the aged and in the presence of sepsis. He has had two deaths, one from asphyxia due to vomiting in a case of intestinal obstruction, the other from coma following great restlessness on recovery of consciousness in an alcoholic. In addition, a few cases have been seriously shocked, and some, especially young people, have been restless. He finds a particular sphere of usefulness for intravenous anaesthesia in the surgery of accidents and fractures, notably where these cases have to be transported for long distances or under difficult conditions—for example, on board ship. He is of the opinion that the method would be of great service in war.

235 Prolonged Anaesthesia with Intravenous Eunarcon

F. SCHRÖDER and O. BÜCKMANN (*Münch. med. Wschr.*, December 10, 1937, p. 1984) observe that although the safety and reliability of short anaesthesia with evipan and eunarcon have been established for some years favourable reports upon prolonged intravenous anaesthesia have been confined to evipan. Their experience with the latter in twenty cases was unsatisfactory; relaxation was poor, prolonged after-sleep or severe excitement often occurred, and large amounts of ether were sometimes used. Examination of the urine after anaesthesia also showed evidence of liver damage. Much better results have been obtained with eunarcon given by their special apparatus. This consists of three interchangeable and sterilizable Record

An Anæsthetic Ether

which answers the tests of the

U.S. Pharmacopœia

German Pharmacopœia

Japanese Pharmacopœia

Dutch Pharmacopœia

French Codex,

and also the extremely severe requirements of the
BRITISH PHARMACOPŒIA, 1932.

HOWARDS' STANDARD ETHER

Laboratory reports show an average boiling point range of not more than 0.2 of a degree (centigrade), and the tests for Aldehydes, Peroxides, etc., prove that *Howards' Standard Ether* is the purest and most consistent Anæsthetic Ether available at the present time.

Used by Government Departments and the principal Hospitals and Institutions throughout the country.

OPTOCHIN for PNEUMONIA

Optochin Base (Howards') has shown remarkable results in the treatment of Pneumonia. Literature will be sent on request.

Howards' products are obtainable from your usual Wholesale House or your Chemist.

HOWARDS & SONS LTD. (EST. 1797), ILFORD

cranial bleedings. The third type of curve, definitely pathological, shows a continued high level for some days, followed by a sudden fall: it may be associated with epileptiform attacks, irritability, somnolence, pyrexia, disinclination for suckling, or other signs of severer degrees of intracranial damage, such as gross haemorrhage. Asphyxial appearances due to birth injury, but not those due to pressure on the cord, are associated with abnormal curves. Braun concludes that measurement of the tension of the fontanelle has a definite value, taken with the clinical signs, in the diagnosis of cerebral injury. He points out also that in a country in which eugenic sterilization for mental disease is practised a record that the patient soon after birth had an increased fontanelle tension may be of importance later.

Pathology

240 Fate of Bone Tissue in Bone Grafts

G. BAHLS (*Beitr. klin. Chir.*, 1937, **166**, 4, 535) points out that there is no unanimity regarding the fate of bone cells in bone grafts. Some authors state that they have a short life, others that they may live for a considerable time but eventually die, others still that most of them live and become connected with the new bone formation. Bahls grafted bone in ten dogs, and examined the grafts carefully at intervals of fourteen days to twenty-one weeks. He found that bone grafts did not remain alive *in toto* even under the most favourable conditions. In all cases the graft was gradually absorbed and replaced by new bone tissue. Most of the bone cells were found to be alive and unchanged even after twelve weeks. He is of the opinion that a bone graft is successful in direct ratio to the length of life of its bone cells. Examination of grafts in human beings showed that (1) grafts may be completely fused with the newly formed bone; (2) that part of the graft may be absorbed; (3) that all but the ends may be absorbed; (4) that a span of bone graft may heal with all its original tissues intact.

241 Serological Reaction in Cancer

M. ARON (*Presse méd.*, October 6, 1937, p. 1403) describes a precipitation or flocculation reaction given by the serum of cancer patients. The antigen is derived from the precipitate obtained by adding 95 per cent. alcohol to urine from cancer cases uncomplicated by tuberculosis or other infections, acute or chronic. The precipitate, as free as possible from albumin and phosphates, is taken up in physiological saline, made alkaline to precipitate phosphates, and filtered; the reaction of the solution is then adjusted to pH 6.8. One portion of this solution is heated to 70° C. and used for the flocculation tests; another portion, heated to 90° C. for thirty minutes, is used for control tests. Dry antigen or concentrated solutions may be prepared for storage. After heating to 57° C. for twenty minutes serum is mixed in varying amounts with test and control antigens and incubated at 38° for sixteen to eighteen hours. As the reactions may not or may only just have begun, the tubes are then left at room temperature and read again twenty-four hours after setting up, when a definite result is obtained, although maximum flocculation is only seen after thirty-six to forty hours. An opalescence or a precipitate in the reaction tubes with clear controls indicates a positive result; the result is negative when all the reaction and control tubes are clear or equally turbid. Cancerous serum appears, therefore, to have two properties: formation of floccules with the active antigen and prevention of floccule formation with the heated antigen. The author concludes that the reaction may form the basis of a diagnostic test for cancer, but because of a few uncertain results out of some hundreds of tests he does not regard its specificity

as absolutely proved. He thinks the reaction is a special case of a general type of reaction given in various diseases. He emphasizes the difficulties of the method and the extreme care necessary in regard to the cleanliness of all apparatus and in the selection of the antigen.

242

Vitamin B in Bread

L. S. FREDERICIA and M. SCHOUSBOE (*Nord. med. Tidskr.*, December 18, 1937, p. 2054) have conducted experiments at the Danish State Vitamin Laboratory in response to a request made in 1936 by the Government health authorities for information as to the content of vitamin B in bread made of rye and wheat. The amount of vitamin B₁ and B₂ in various kinds of Danish bread was estimated by the rat-growth method as modified by H. Krieger Lassen. The term "vitamin B₂" was applied to all the vitamins in yeast belonging to the B group with the exception of B₁ and perhaps B₆. The quantity of vitamin B₁ was given in international units, and that of B₂ in the units employed by Krieger Lassen. The vitamin content was recorded per 100 grammes of fresh bread containing about 40 per cent. moisture. It was found that baking had no appreciable influence on the content of vitamin B₁ and B₂ in bread. Whole-meal wheat bread, milled to 97 per cent., was found to contain 82 to 87 international units of vitamin B₁, and common white wheat bread, milled to 55 per cent., contained 24 to 27 international units of vitamin B₁. Wheat bread of meal milled to 69 per cent. contained 35 international units. Coarse rye bread, milled to 100 per cent., and fine light rye bread, milled to 80 per cent., contained 50 to 55 international units of vitamin B₁. Wheat middlings and rye middlings contained respectively 591 and 252 international units of vitamin B₁; they were, therefore, well suited to increase the vitamin content of bread. After giving the corresponding figures for vitamin B₂ the authors conclude that the vitamin B₁ requirement of the Danish population seems only to be partly met by the bread at present available.

243

Pneumonia due to *B. friedländeri*

J. BULLOWA, J. CHESSE, and N. FRIEDMAN (*Arch. intern. Med.*, November, 1937, p. 735) state that *B. friedländeri* is the sole causative agent in a definite but relatively small proportion of pulmonary infections. Forty-one patients with pneumonia due to this organism were studied at the Harlem Hospital during the seven-year period from 1929 to 1936. The bacillus was recovered either from the blood or by pulmonary suction as well as from the sputum. Signs and symptoms were usually similar to those of pneumonia due to the pneumococcus, but occasionally a patient presented no physical signs in spite of extensive involvement revealed by x-ray or post-mortem examination. In two-thirds of the cases the sputum was like that of pneumococcal lobar pneumonia, but the remaining third had sputum said to be typical of *B. friedländeri* pneumonia, being thick, gelatinous, and diffusely bloody, and expectorated copiously but with difficulty. Some had free haemoptysis, some a thin sputum like currant jelly. The shortest duration of illness from onset to death was thirty hours, and the average five and a half days. (Patients with pneumococcus II pneumonia treated during the same period showed an average duration from onset to death of nine days.) The death rate of the entire group was 83 per cent. The highest mortality rate (94 per cent.) occurred in patients infected with *B. friedländeri* A who were not given serum. Of six patients with a *B. friedländeri* infection who were given specific serum, three died—a mortality rate of 50 per cent. The authors recognize that their cases are too few for definite conclusions to be drawn as to the value of serotherapy, but they suggest that, in view of the fulminating nature and high mortality of this type of pneumonia, serum should be administered early in the course of the disease, as soon as the easily recognized *B. friedländeri* is found and typed.

HOW IMPORTANT ARE MINERALS IN THE DIET?

They are absolutely essential for the maintenance of an adequate state of nutrition. However, not infrequently an apparently minor mineral deficiency may weaken the body's defensive mechanism to such a point that

Pregnancy, Infection, or
any other unusual tax

may lead to a prolonged period of convalescence.

THE ABSOLUTE COMFORT and security which the Deimel Underwear affords in the most trying climate is remarked upon by all its wearers. Those whose powers of resistance have been weakened by wearing unsuitable underwear derive new strength from Deimel Mesh Garments which absorb and eliminate perspiration quickly, and provide a dry climate about the body which enables the wearer to undergo extremes of heat and cold with comfort.

REMARKABLE RESULTS IN A WIDE RANGE OF SKIN DISEASES

Physicians' reports show that the BELZEMA treatment gains controlling power over the progress of many difficult skin disorders, including those of microbic and parasitic etiology. Many of the cases concern lesions which had previously been unresponsive to more commonly employed treatments. Furthermore, these results have a gratifying permanency.

These untouched photographs illustrate a case of Psoriasis of fifteen years' duration which was pronounced incurable. Many treatments were employed, bringing no response. Finally BELZEMA Ointment and BELZEMA Soap were prescribed by an eminent dermatologist. The result was complete elimination of the complaint in 26 days. The camera has convincingly portrayed the therapeutic action of BELZEMA Ointment and BELZEMA Soap. We believe that your confidence in BELZEMA will be established soundly after a clinical trial.

Advantages possessed by

BELZEMA
BRAND OINTMENT

- Complete Rapid Absorption
- Immediate Pruritic Relief
- Ease of Application
- Positive Results
- No Bandaging Required

INDICATIONS. ECZEMA, PSORIASIS, ALOPECIA, RINGWORM, DANDRUFF, ACNE and other skin disorders.

BELZEMA publicity is confined absolutely to the Medical Profession and the fullest co-operation of its manufacturers and ourselves may be expected.

"We guarantee to alter exchange or accept the return of any appliance without cost ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

For chronic ulceration of the leg—

SALTAIR

ELASTIC PLASTER

BANDAGES

For chronic ulceration of the leg, varicose veins, etc., SALTAIR ELASTIC PLASTER BANDAGES constitute the latest and most successful treatment. These Bandages have highly elastic properties and are impregnated with an antiseptic zinc oxide paste. Self-adhesive, shaping to the limb. Give firm, equable support, stimulating the ulcer to healthy repair. Promote correct circulation and reduce oedema. An ideal ambulatory treatment, allowing for full activity of the limbs, with results that have proved to be better than those achieved following rest in bed alone. (Saltair Elastic Plaster Bandages are also extremely effective as abdominal support after operation, as a strapping for the breast in mastitis, and as dressings for minor injuries, boils, etc.)

POCKET VALVE DEAF AID!

BONOCHORD High Fidelity Amplifiers are preferred by all who demand the best obtainable in hearing aids.

Here is a new model which can be worn on the person, while in no way sacrificing the high quality of reproduction for which BONOCHORD Amplifiers are recommended by medical men.

Frequency response is from 200 to 8,000 cycles per second. A Piezo-electric microphone and three stages of amplification are employed, also automatic volume-control and noise-suppression. The aid is entirely dry battery operated, with flash lamp cells for low tension which are obtainable everywhere.

All models are available for home trial. Any BONOCHORD instrument will be sent for clinical test free of charge, on request. Send for the BONOCHORD booklet, *The Hearing Aid Par Excellence*, giving full details, illustrations, and prices of all models.

STRETTON HOUSE, Church Stretton, Shropshire.

A PRIVATE HOME for the treatment of Gentlemen suffering from Mental and Nervous Illness, including the allied disorders of Alcoholism and Drug Habit. All types of early Mental and Nervous cases are received without certificates as Voluntary Patients under the provisions of the Mental Treatment Act, 1930, draining hill country. See Medical Directory, p. 2328. Apply to the Medical Superintendent. Phone: 10 P.O. Church Stretton.

ST. ANDREW'S HOSPITAL FOR MENTAL DISORDERS NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: The Most Hon. THE MARQUESS OF EXETER, C.M.G., A.D.C.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients and certified patients of both sexes, are received for treatment. Careful clinical, pathological, bacteriological, and pathological examinations. Private rooms, with special nurses, made available in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical Bath, Plombage treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for bacteriological, bacteriological and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 100 acres. All great fruit and vegetables are supplied to the Hospital from the farm gardens, and a variety of Moulton Park. Occupational Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 350 acres, Llanarthfael, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton) who can be seen in London by appointment.

HAYDOCK LODGE

NEWTON-LE-WILLOWS, LANCASHIRE

Tele: Street, Ashton-in-Makerfield.

Phone: Ashton-in-Makerfield 7311.

Tel.: SALISBURY 2612.

The CLINIC

ADDITIONS AND IMPROVEMENTS—

More than £12,000 spent
in two years!
(Over £7,000 in 1936, over £5,000
in 1937.)

These improvements embraced Catering Services, equipment, furniture, etc., and an entire re-organisation of the Nursing Service.

The Trustees of The Clinic, Devonshire Place, W.1, extend a cordial invitation to Medical Practitioners to visit the Nursing Home and inspect the various improvements in equipment and services recently carried out.

Over £12,000 was expended on these during the past two years—that sum representing the surplus apart from ordinary maintenance expenses—in accordance with the provisions of the present Company's Constitution.

Of especial interest to the Medical Profession is the entire re-organisation of the Nursing Service (comprising over 160

State-registered nurses), to which a great deal of thought and work, as well as considerable expense, has been devoted.

An important service feature is the free dispensary service which now operates, without any increase of room-rates, for the benefit of all patients.

Please write to the Secretary for full details, or arrange a visit at your own convenience.

There are eight operating theatres in The Clinic. The room rates, which range from 10 gns. to 18 gns. (apart from a few suites at 25 gns. to 42 gns.), average no more than 14 gns.

The CLINIC 20, DEVONSHIRE PLACE, LONDON, W.1.

Telephone: WELbeck 444 (20 lines)

NEW LODGE CLINIC, WINDSOR FOREST

This Clinic was founded in 1921 in order to provide for the scientific investigation and treatment of disease by a "team" of physicians and specialists.

All forms of non-infectious medical cases are admitted, special attention being paid to disorders of digestion and metabolism, arthritis, anaemias, asthma, heart and kidney disease, and functional and organic nervous disorders.

Particulars can be obtained on application to the Secretary, New Lodge Clinic, Windsor Forest, Berks.
Telephone: 181 and 182 Winkfield Row.

SHAFTESBURY HOUSE,

FORMBY-BY-THE-SEA,
Nr. Liverpool.

UNIVERSITY OF DURHAM

THE MEDICAL SCHOOL,

KING'S COLLEGE, NEWCASTLE UPON TYNE

(formerly the University of Durham College of Medicine).

The degrees in Medicine, Surgery, Hygiene, and Dentistry, the Diploma in Public Health, the Diploma in Psychiatry, and the Licence in Dental Surgery of the University of Durham are open to men and women.

The SUMMER SESSION, 1938, will be commenced on THURSDAY, APRIL 21st.

At the Medical School, King's College, Newcastle upon Tyne, students can complete the entire course of professional study required for the above degrees, diplomas, and licence; also for the Examinations of the Royal Colleges of Physicians and Surgeons and other Examining Bodies.

Hospital practice is carried out at the Royal Victoria Infirmary, a general hospital containing more than 700 beds, and there are facilities for the study of the various special subjects. General and Special Post-graduate Courses are held.

Practical Midwifery can be studied at the Princess Mary Maternity Hospital, which contains 90 beds, with an annual indoor and outdoor attendance on 3,000 cases. Lectures are given on Psychological Medicine in the Medical School, and clinical instruction at the Mental Hospital, Newcastle. Clinical instruction in Infectious Diseases is given by the Medical Officer of Health in the City Hospital at Walkergate.

The Dental Department includes a dental hospital equipped on the most modern lines, with abundant material for clinical teaching and facilities for training in practical dental mechanics.

Particulars may be obtained from the Dean of Medicine, Medical School, Northumberland Road, Newcastle upon Tyne, 1.

LIGHT THERAPY TREATMENT. X-RAY DEPARTMENT.

Classes held twice a year for post-graduates by arrangement with the Fellowship of Medicine.

All enquiries should be addressed to The Secretary.

ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in July, 1938.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty.

At the end of three years' service, officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Full opportunities exist for transfer to the permanent list, and periods of unemployed or half pay are very rare. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances.

Opportunities are available for officers on the permanent list for post-graduate study, to specialise, to take higher examinations and to obtain further qualifications.

Copies of the regulations for entry and conditions of Service, including rates of pay, allowances and retired pay may be obtained from the Medical Director-General of the Navy, Admiralty, S.W. 1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than 31st May, 1938.

DERBYSHIRE COUNTY COUNCIL. WOMAN ASSISTANT MATERNITY AND CHILD WELFARE MEDICAL OFFICER.

The Derbyshire County Council require the services of a fully qualified whole-time woman Assistant Maternity and Child Welfare Medical Officer, experienced in Ante-Natal work, Midwifery and Children's Diseases, to hold (under the direction of the County Medical Officer of Health) consultations at the Ante-Natal and Maternity and Child Welfare Centres of the Derbyshire County Council and (under the like direction) to perform such other duties as appertain to the office.

The salary will be £600 per annum, rising by £25 per annum to £650 per annum.

The appointment will be a designated post under the Local Government and Other Officers' Superannuation Act, and the successful candidate will be required to pass a medical examination.

Forms of application may be obtained from the undersigned, to whom they must be returned, together with copies of not more than three recent testimonials, not later than April 4th, 1938.

W. M. ASH,

New County Medical Officer of Health.

St. Mary's Gate, Derby.
March 10th, 1938.

BOROUGH OF DUKINFIELD. TEMPORARY PART-TIME APPOINTMENT OF MEDICAL OFFICER OF HEALTH.

Applications are invited for the temporary part-time appointment of Medical Officer of Health for the Borough of Dukinfield.

The officer appointed will be required also to carry out the duties of School Medical Officer. The salary paid will be at the rate of £400 per annum.

The appointment will be a temporary one until September 25th, 1938, or until terminated by one month's notice in writing by either side, whichever is the earlier.

Consenting will be a disqualification. Further particulars and forms of application may be obtained from the undersigned, to whom forms of application must be returned before March 26th, 1938.

Town Hall, Dukinfield.
March 11th, 1938.

ERNEST BARLOW,

Town Clerk.

COUNTY BOROUGH OF TYNEMOUTH PUBLIC ASSISTANCE COMMITTEE PRESTON HOSPITAL, North Shields. (430 Beds.)

ASSISTANT MEDICAL OFFICER (WOMAN) NON-RESIDENT.

The Council of the County Borough of Tynemouth invites applications from qualified and registered Medical Practitioners for the appointment of a woman Assistant Medical Officer at the above Hospital for a period of six months, extendable to a maximum period of twelve months, as from April 1st, 1938.

The salary will be £200 per annum, plus emoluments to the value of £110 per annum. The Officer appointed will be required to refund to the Council all fees received by her.

The appointment will be subject to one month's notice on either side.

The Officer appointed will be required to submit a satisfactory Medical Certificate, to devote the whole of her time to her official duties, and to act under the direction of the Medical Officer.

Applications, stating age, experience and qualifications, accompanied by not more than three recent testimonials, and endorsed "Assistant Medical Officer," must be delivered to the undersigned not later than March 23rd, 1938.

Further information may be obtained from the Medical Officer, Preston Hospital, North Shields. Candidates, either directly, or indirectly, will be a disqualification.

FRED G. EGNER,

14, Northumberland Square, Tynemouth.
North Shields.
March 5th, 1938.

COUNTY BOROUGH OF PRESTON. SHAROE GREEN HOSPITAL. (250 Beds.)

JUNIOR ASSISTANT RESIDENT MEDICAL OFFICER (FEMALE).

Applications are invited from fully qualified and registered Practitioners for the above appointment. Salary at the rate of £100 per annum, with full board and residence. The appointment will be for a period of six months and can be renewed for a period not exceeding six months.

Applications, stating age, qualifications and experience, together with copies of three recent testimonials, should reach the Medical Superintendent not later than first post on March 26th, 1938.

CITY AND COUNTY OF BRISTOL. BARROW HOSPITAL.

SECOND ASSISTANT MEDICAL OFFICER (MALE).

Applications are invited for the position of Second Assistant Medical Officer (male) at the above-named Hospital.

The salary offered is £200 per annum, rising by four annual increments of £25 to £250 per annum, plus full residential emoluments valued for superannuation purposes at £150 per annum; in addition £50 per annum will be paid for the D.F.M.

Candidates should be of British nationality, under 35 years of age and unmarried. Preference will be given to candidates with previous general and mental hospital experience.

The Hospital is a complete modern unit situated 15 miles from Bristol, with a full consultant staff and every facility for treatment and research.

Applications, accompanied by two testimonials, a statement of particulars and experience and a photograph should be sent to the Medical Superintendent, Bristol Mental Hospital, Fildrass, Bristol, not later than April 1st, 1938.

JOSIAH GREEN,

Clerk to the Visiting Committee.

The Council House,
Bristol, 1.
March 12th, 1938.

LANCASHIRE COUNTY COUNCIL. BIDDULPH GRANGE ORTHOPAEDIC HOSPITAL.

Applications are invited from duly qualified and registered medical practitioners for the post of ASSISTANT VISITING ORTHOPAEDIC SURGEON at the above Hospital, which amounts to £250 per annum.

Candidates must have had special training and experience in orthopaedic surgery, and must possess the diploma of F.R.C.S. (Eng.). The successful candidate will be required to visit the Hospital twice weekly. The appointment will be for a period of three years, terminable by one calendar month's notice on either side.

Applications, with copies of two recent testimonials, should be sent not later than April 2nd, 1938, to Dr. F. Hall, School Medical and Child Welfare Department, County Offices, Preston.

GEORGE EATHERTON,

Clerk of the County Council.

COUNTY COUNCIL OF DURHAM. ASSISTANT WELFARE MEDICAL OFFICER.

The County Health Committee invite applications for an Assistant Welfare Medical Officer (woman) at a commencing salary of £500 per annum, rising by annual increments of £25 to £700 per annum. Travelling allowance will be paid by the County Council in accordance with a scale to be approved from time to time.

The appointment will be held subject to three calendar months' notice on either side, and to the following conditions:

(1) The Officer appointed must be a registered medical practitioner between the ages of 25 and 55 years, must devote the whole of her time to the duties of the office, and must not engage in private practice.

(2) She should either have had a previous appointment as Medical Officer of an ante-natal clinic, with the approval of the Minister of Health, or have had at least three years' experience in the practice of her profession and special experience of practical midwifery and ante-natal work. The holding of a diploma in Public Health will be deemed an additional qualification for the post.

(3) She will be subject to the directions of the County Medical Officer of Health.

(4) She will be required to reside in Durham City, or such other place as required by the Council.

(5) She must be prepared, if called upon, to act as locum tenens to other members of the medical staff of the County Medical Officer of Health.

(6) The appointment will terminate on marriage.

(7) The candidate appointed will be required to pass the County Council's medical examination, and will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Applications, endorsed "Assistant Welfare Medical Officer," with copies of not more than three recent testimonials, must be addressed to the County Medical Officer of Health, Shire Hall, Durham, and must be received by him not later than Monday, March 28th, 1938.

Shire Hall, J. K. HOPE,
Durham, Clerk of the County Council.
March 5th, 1938.

COUNTY COUNCIL OF DURHAM. APPOINTMENT OF TEMPORARY ASSISTANT MEDICAL OFFICER OF HEALTH

Applications are invited for the post of Temporary Assistant Medical Officer of Health (male), at a commencing salary of £600 per annum. The appointment is subject to one month's notice on either side, and will terminate at the end of two years. Travelling and subsistence allowances will be paid in accordance with the Council's scale.

Applicants must be registered medical practitioners under the age of 55 years, and should if possible possess a qualification in Public Health and have held a post in an Infectious Diseases Hospital. Experience in the examination and certification of mentally defective children and adults will be an additional recommendation.

The officer appointed will be required to devote the whole of his time to the duties of the office, and will not be allowed to engage in private practice. He will also be required to undertake such other Public Health duties as may be allotted to him by the County Medical Officer of Health, under whose direction he will work.

Applications, stating age, qualifications and experience, and accompanied by copies of not more than three recent testimonials, should be forwarded to the County Medical Officer of Health, Shire Hall, Durham, not later than first post on Monday, March 28th, 1938.

Shire Hall, J. K. HOPE,
Durham, Clerk of the County Council.
March 5th, 1938.

BOROUGH OF ACCRINGTON. DEPUTY MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER.

Applications for the above post are invited from registered medical practitioners of either sex. Candidates should have had sound post-graduate experience in general clinical work, including the diseases of children, and preference will be given to a person possessing a Diploma in Public Health or an equivalent registrable qualification.

The officer appointed will be required to carry out duties in all branches of the Public Health and School Medical Services, including both clinical and administrative work. He, or she, will work under the direction of the Medical Officer of Health and will act as that officer's Deputy.

The salary will be at the rate of £500 per annum, rising by annual increments of £25 to a maximum of £700 per annum. The post will be designated for superannuation purposes.

Forms of application and particulars of the appointment and its terms and conditions may be obtained from the undersigned, to whom the completed form must be returned not later than Monday, March 28th, 1938.

Town Hall, Accrington, Town Clerk.
March 9th, 1938.

COUNTY OF DORSET. APPOINTMENT OF COUNTY PATHOLOGIST.

The Dorset County Council invite applications from registered medical practitioners for the appointment of a County Pathologist, at a commencing salary of £750 per annum, rising to £950 by biennial increments of £50.

Applicants must have specialized in Pathology and Biochemistry, and have had considerable experience in a Pathological Department.

The Officer appointed will be required to devote his whole time to the duties of his office, and will be in charge of the work of the County Laboratory, Dorchester, acting under the administrative control of the County Medical Officer.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass the necessary medical examination.

Applications, on a prescribed form, which may be obtained from me on receipt of a stamped addressed foolscap envelope, must be forwarded so as to be received not later than Monday, April 4th, 1938.

Canvassing, either directly or indirectly, will be a disqualification.

County Offices, C. P. BRUTTON,
Dorchester, Clerk of the County Council.
March 4th, 1938.

COUNTY BOROUGH OF GRIMSBY. Corporation Hospital and Sanatorium.

RESIDENT MEDICAL OFFICER.

Applications are invited for the post of RESIDENT MEDICAL OFFICER (male) at the above Hospital, which has 98 beds for pulmonary and surgical tuberculosis and 72 for infectious diseases.

Candidates must be unmarried and have previous resident hospital experience. Salary £350 per annum, rising by annual increments of £25 to £450 per annum, plus board, residence and laundry. The appointment is to be for one year in the first instance. The post is a designated one under the Local Government and Other Officers' Superannuation Act, 1922.

Forms of application may be obtained from the Medical Officer of Health, 184, Victoria Street, Grimsby, and should be returned to me endorsed "Resident Medical Officer," not later than Thursday, March 31st, 1938.

JOHN W. JACKSON,
Municipal Buildings, Town Clerk.
170 Victoria Street, Grimsby.

KENT COUNTY COUNCIL. RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited for the post of Resident Assistant Medical Officer at the County Hospital, Farnborough (880 beds).

The salary for the appointment is £250 a year, with residential emoluments which are valued at £120 a year.

The appointment is a whole-time one and will be for a period of one year only, and not renewable.

Forms of application can be obtained from the Public Assistance Officer, Tonbridge Road, Maidstone, to whom applications must be sent by 10 a.m. on Monday, March 28th, 1938.

Sessions House, W. L. PLATTS,
Maidstone, Clerk of the County Council.
March 12th, 1938.

CITY OF LINCOLN. RESIDENT MEDICAL OFFICER.

Applications are invited for the appointment of Resident Medical Officer, male, unmarried, at the City Hospital and Sanatorium, for a period of 12 months, from registered medical practitioners.

Salary £300 per annum, with board, lodging and laundry. Applications must be made on the prescribed forms not later than March 24th, 1938.

Forms of application and further particulars of the appointment may be obtained from the undersigned.

City Health Department, M. L. BERY,
Beaumont Fee, Medical Officer of Health,
Lincoln.

BOROUGH OF BARKING. ASSISTANT MEDICAL OFFICER (MALE).

Applications are invited, before April 4th, 1938, from qualified medical practitioners, with experience in public health work and a registrable qualification in public health, for the designated appointment of Assistant Medical Officer of Health and Assistant School Medical Officer.

Salary scale £600-£25-£700.
Particulars of duties and application form may be obtained from the undersigned.

Town Hall, S. A. JEWERS,
Barking, Essex, Town Clerk.
March 12th, 1938.

ADMINISTRATIVE COUNTY OF ESSEX. APPOINTMENT OF ASSISTANT SPECIALIST OPHTHALMIC SURGEON.

The County Council of the Administrative County of Essex invite applications for the above appointment from Registered Medical Practitioners, not over 45 years of age, with special experience in all branches of ophthalmology and preferably holding the Diploma in Ophthalmic medicine, to act under the County Medical Officer of Health.

The salary will be at the rate of £700 per annum, and will rise, subject to satisfactory service, by annual increments of £25, to £800 per annum.

The person appointed will, at the discretion of the Council, either be provided with a car or will be paid a travelling allowance in accordance with the County Scale for the time being in force.

The person appointed will be required to devote his whole time to the service of the Council, and to perform such duties and to furnish such advice and assistance appertaining to his office as may be required, and to reside in such district of the County as the Council may decide. The appointment will be held by the successful candidate during the pleasure of the Council, and will be determinable by the Officer by three months' notice in writing.

The person appointed will be required to pass a medical examination and to contribute 5 per cent. of his salary to the fund established by the County Council under the Local Government and Other Officers' Superannuation Act, 1922.

The appointment will be subject to the Council's Sick Pay Rules and Regulations, a copy of which will be forwarded on application.

Applications on the prescribed form, obtainable from the undersigned, and accompanied by copies of not more than three testimonials, which will not be returned, should be addressed to me and delivered at the County Hall, Chelmsford, not later than 10 a.m. on Friday, March 25th, 1938.

E. S. HOLCROFT,
Clerk of the County Council.
County Hall, Chelmsford.
March 7th, 1938.

COUNTY BOROUGH OF BLACKBURN. LADY ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from duly registered women practitioners for the appointment of Assistant Medical Officer of Health and Assistant School Medical Officer to act under the direction and supervision of the Medical Officer of Health, who is also School Medical Officer.

The maximum salary will be £700 per annum. The commencing salary will not be less than £600 per annum, and will be fixed according to the qualifications and experience of the successful applicant, and will rise by annual increments of £25 to the maximum of £700.

The person appointed must have had at least three years' postgraduate experience in the practice of her profession and special experience of midwifery and ante-natal work. Special post-graduate experience in the treatment of venereal diseases and of diseases of children, and the possession of a registrable degree or diploma in Public Health will be deemed additional qualifications.

Applications to be made on forms to be obtained from the Medical Officer of Health, Victoria Street, Blackburn, and returned to him not later than Wednesday, March 23rd, 1938, endorsed "Assistant Medical Officer of Health."

Canvassing, directly or indirectly, will be a disqualification.

Town Hall, CHAS. S. ROBINSON,
Blackburn, Town Clerk.
March 7th, 1938.

COUNTY BOROUGH OF BRIGHTON. BRIGHTON MUNICIPAL HOSPITAL.

RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited for the above appointment. Candidates must be single men, who have held resident appointments in a General Hospital.

The officer appointed will work under the direction of the Medical Superintendent, and will devote his whole time to official duties, which are primarily for obstetrical work.

The appointment is a whole-time one, and is for one year only.

Salary £300 per annum, together with residential allowances, valued for the purposes of superannuation at £150 per annum.

The post is designated under the Local Government and Other Officers' Superannuation Act, 1922.

Forms of application, conditions of appointment and list of duties may be obtained from the undersigned, which forms, duly completed, and accompanied by copies of testimonials, must be returned to the Medical Superintendent not later than Wednesday, March 30th.

Canvassing the Committee, either personally or by letter, will be considered a disqualification for appointment.

APPOINTMENTS.—Contd.

BRISTOL DISPENSARY.

The Committee are prepared to appoint a NON-RESIDENT MEDICAL OFFICER on the Staff of this Institution.

Candidates must be duly registered according to the provisions of the Medical Acts, and not over the age of 35.

The candidate appointed will be required to commence duty on May 15th.

Each candidate must give his or her time to the services of the Institution in such a way as may be directed. The Committee may give permission for private practice.

For particulars apply to the Secretary, to whom testimonials must be sent on or before April 5th. Card, with address, should be enclosed.

47, St. Nicholas Street. H. MERRETT STOCK, Bristol.

March 11th, 1938. Secretary

WILSON HOSPITAL, MITCHAM, SURREY. (12 Beds.)

RESIDENT MEDICAL OFFICER (male or female) required from March 31st next. Salary £150 per annum, with board, residence and laundry. The appointment is for six months, renewable for a further six months at the discretion of the Committee.

The Hospital is quite modern and exceptionally well equipped, and carries out work of a character which gives the Resident Medical Officer a considerable amount of experience.

Applications, with copies of three testimonials, stating age, qualifications and experience (particularly anaesthetics), should be sent at once to the Hon. Secretary, "Greenvale," Lower Green, Mitcham.

WEST KENT GENERAL HOSPITAL (Incorporated), Maidstone. (135 Beds.)

Applications are invited for the post of HOUSE SURGEON, who must be a male of British nationality and unmarried. Salary at the rate of £175 per annum, with board, apartments and laundry. Candidates must possess registered qualifications.

Applicants, stating qualifications and experience, together with copies of testimonials, should be sent to the undersigned on or before March 31st, 1938. The successful candidate will be required to take up residence in early April.

EDWARD J. GREGG, House Governor and Secretary.

WINGFIELD-MORRIS ORTHOPAEDIC HOSPITAL, Headington, Oxford.

HOUSE SURGEON (male) required for six months from May 1st. Salary at the rate of £100 per annum, with board, lodging and laundry.

Applications (with testimonials) to be sent on or before April 1st to Professor Girdlestone.

WALSALL GENERAL HOSPITAL.

The Committee will shortly proceed to the appointment of an ASSISTANT HON. SURGEON to the Ear, Nose and Throat Department.

Applications, with the necessary particulars, should be made to the undersigned.

WALTER FRANKCOMBE, House Governor.

March 14th, 1938.

DEVONSHIRE ROYAL HOSPITAL.

Buxton, Derbyshire. (300 Beds.)
(A National Hospital for Rheumatism and Allied Diseases.)

RESIDENT MEDICAL OFFICER (male), salary £200 per annum, or **HOUSE PHYSICIAN** (male), salary £150, rising to £175 after three months' service (and prospects of promotion to Resident Medical Officer), with board-residence and laundry. Candidates must be fully qualified and registered. The appointments are for a minimum period of six months, and may be extended for a further period of six months.

Applications, endorsed "Medical Appointments," stating age, experience and qualifications, and whether application is made for one or either post, together with copies of three recent testimonials, must be forwarded without delay to the undersigned, from whom any further particulars may be obtained.

Considerable orthopaedic experience is available, and the appointments offer special facilities for gentlemen preparing a thesis or wishing to undertake special work, as the Hospital contains all the necessary laboratory and other facilities for research. Canvassing will disqualify.

By Order of the Committee of Management,
A. PRESTON-TURNER,
General Superintendent and Secretary.

DONCASTER ROYAL INFIRMARY AND DISPENSARY. (185 Beds.)

HONORARY ORTHOPAEDIC SURGEON.

The Board of Management propose to establish an Orthopaedic Department at the Doncaster Royal Infirmary. Applications are invited from gentlemen with Special Orthopaedic experience to take charge of the Department.

An Honorarium of £250 per annum and upwards will be paid according to the amount of time the surgeon proposes to devote to the work. The successful candidate will be restricted to the practice of Orthopaedic Surgery, and must hold a higher Surgical or Orthopaedic qualification.

The appointment is subject to confirmation by the annual meeting of Governors. Canvassing, either directly or indirectly, will disqualify.

Sixty copies of the application, together with copies of three recent testimonials, must be furnished, and should be forwarded to the undersigned not later than April 4th, 1938.

R. LANCASTER,
Secretary-Superintendent.

MANCHESTER AND SALFORD HOSPITAL FOR SKIN DISEASES.

(54 Beds 14,500 Out-patients per annum.)

HOUSE SURGEON.

Applications are invited for the post of House Surgeon. Must be registered. The appointment is for six months. Salary at the rate of £150 per annum, with board and residence.

Applications, with copies of three testimonials, to be sent to the undersigned, Quay Street, Manchester.

JOHN NALL, Secretary.

BURSLEM HAYWOOD AND TUNSTALL WAR MEMORIAL HOSPITAL.

High Lane, Tunstall, Stoke-on-Trent.
(66 Beds. Approved Training School for Nurses.)

Applications are invited for the post of **RESIDENT HOUSE SURGEON**. Salary £175 per annum, with board, residence and laundry.

The appointment is for six months in the first instance, reappointment may be applied for. Applications, stating age and experience, with copies of three recent testimonials, to be sent to the undersigned immediately.

C. E. LOWNDES,
Secretary.

HOVE GENERAL HOSPITAL, HOVE.

(53 Beds.)

Applications are invited for the appointment of **JUNIOR RESIDENT MEDICAL OFFICER** (male). Salary £120 p.a., with board, apartments and laundry. The successful applicant will, if suitable, be eligible to apply for the senior post which becomes vacant six months later.

Applications, stating age and qualifications, together with three recent testimonials, to be forwarded to the undersigned.

K. C. BOOKER,
Secretary-Superintendent.

HOUNSLOW HOSPITAL, MIDDLESEX.

Applications are invited for the post of **JUNIOR CASUALTY OFFICER** and **HOUSE PHYSICIAN**. Salary £100 per annum, with board, residence and laundry. The appointment is for six months, and applications, stating age, nationality and qualifications, should be sent, with copies of three recent testimonials, to the Secretary.

ROYAL HOSPITAL, RICHMOND, SURREY

Applications are invited immediately for the following posts:—

SENIOR HOUSE SURGEON (male), £150 per annum.

JUNIOR HOUSE SURGEON (male), £100 per annum.

In the case of the Senior appointment, the Hospital is officially recognized for the surgical practice required before admission to the Final Fellowship Examination of the Royal College of Surgeons of England.

Board, furnished apartment and laundry. Candidates must be fully qualified, registered and single. Form of application can be obtained from the undersigned.

G. M. EDEN,
Secretary-Superintendent

THE ROYAL CRIPPLES HOSPITAL, BIRMINGHAM.

(306 Beds and large Out-Patient Department.)

Applications are invited for the post of **RESIDENT HOUSE SURGEON** (male), vacant April 1st next. Salary £200 per annum, plus car allowance. The appointment, which is for a period of six months, is renewable on the discretion of the Medical Board, and is terminable by one month's notice on either side.

Candidates must be unmarried, and preference will be given to those with previous experience in General and Orthopaedic Hospitals.

Applications, with copies of three recent testimonials, to be sent on or before March 26th, 1938, to the General Secretary, Royal Cripples Hospital, 80, Broad Street, Birmingham, 15.

WEST SUFFOLK GENERAL HOSPITAL,

Bury St. Edmund's. (112 Beds.)

Applications are invited for the post of **HOUSE SURGEON**. Duties include charge of the Surgical beds. Salary £180 per annum, with board, lodging and laundry.

One other Resident Medical Officer. Applicants must be registered practitioners.

Applications, stating age, experience and nationality, with three copies of three recent testimonials, to be sent to the Secretary. The vacancy occurs April 1st, 1938.

E. E. HARDWICKE,
Secretary.

THE CHESTER ROYAL INFIRMARY.

(225 Beds.)

TWO HOUSE SURGEONS (male).

Applications are invited for the above posts, to take up duty on April 1st, 1938. Salary £150 per annum, with board, lodging and laundry. The appointments are approved in connexion with the M.S. (London University) and F.R.C.S. (Eng.) Examinations. Application list closes March 25th, 1938. Application forms may be obtained from **W. H. GRACE, M.D., M.R.C.P.,** Hon. Secretary, Medical Committee.

OXTED AND LIMPSFIELD COTTAGE HOSPITAL,

Oxted, Surrey.

HONORARY EAR, NOSE AND THROAT SURGEON.

The Board of Management invites applications for the above post.

Applications must reach the undersigned by Saturday, March 26th.

F. W. WALPOLE, Secretary.

PORTSMOUTH AND SOUTHERN COUNTIES EYE AND EAR HOSPITAL,

Pembroke Road, Portsmouth.

HOUSE SURGEON (Male).

Applications are invited from registered medical practitioners for the above post vacant on April 1st. Salary £150 p.a., plus board and lodging.

Applications, giving particulars of age, experience and nationality, together with copies of recent testimonials, to be addressed to the Secretary not later than March 31st, 1938.

KENT AND CANTERBURY HOSPITAL.

The Board of Management invite applications from duly qualified Medical Practitioners for the post of **HONORARY ANAESTHETIST** to the Ear, Nose and Throat Department. Particulars of the appointment may be obtained from the undersigned, to whom applications, accompanied by testimonials, should be forwarded not later than April 11th, 1938.

J. F. KENT,
Superintendent and Secretary.

Well-situated house with 2 reception, 6 bedrooms, etc., on rental. Smaller house if wished. Premium £2,600, payable by instalments, as arranged.
13. **LONDON, SOUTH-EAST**.—Old established PRACTICE worked as a lock-up producing between £650 and £700 p.a., of which £450 is from Panel and P.M.S. Suitable surgery premises on rental. Large scope for increase by anyone devoting full time to the work.
14. **SOUTH WALES**.—Old established PRACTICE held by vendor (who is taking up an appointment) 13 years. Gross cash receipts over £1,800 p.a., chiefly derived from Panel and appointments. House has ample accommodation. Premium 2 years' purchase, or near offer.
15. **EASTERN COUNTIES**.—COUNTRY TOWN. PARTNERSHIP. A ONE-QUARTER SHARE (with increase later) is offered in old-established PRACTICE producing about £3,000 p.a., including large Panel. Suitable accommodation can be obtained. Premium £1,500, payable by instalments.
16. **HOME COUNTIES**.—FAVOURITE RESIDENTIAL TOWN WITHIN EASY REACH OF LONDON. A ONE-HALF SHARE, estimated to produce about £1,000 p.a., is offered in increasing good mixed-class PRACTICE having good scope for further development. Selected Panel of 475. Low expenses. Good house with 2 reception, 4 bedrooms, etc., on rental. Premium £1,700. Incoming partner should be about 30-35, married, and preferably experienced in surgery.
17. **SOUTH-WEST LONDON**.—Mixed-class PRACTICE producing between £800 and £900 p.a. Panel of nearly 500. House can be rented at £100 p.a., inclusive. Reasonable offer accepted for quick sale owing to vendor's ill-health.
18. **LADY DOCTOR'S PRACTICE**.—LONDON, SOUTH-WEST. Chiefly middle-class PRACTICE producing for last 12 months over £1,000. Panel of 268. Well-situated house with ample accommodation. Price £1,350. Premium 1½ years' purchase.
19. **EASY REACH OF CENTRAL LONDON**.—Old established mainly working-class PRACTICE held by vendor (who is now retiring) many years. Average gross cash receipts for last 3 years over £1,700 p.a. (last year over £1,800). Large panel. Suitable house with 2 sitting, 3 or 4 bedrooms, professional accommodation. Can be rented on lease.
20. **SUSSEX**.—FAVOURITE RESIDENTIAL TOWN. PARTNERSHIP. A ONE-HALF SHARE is offered in good-class practice situated in very attractive district, producing about £3,200 p.a. Panel of about 1,200. Well-built modern house can be rented at £150 p.a. Premium 2 years' purchase. Incoming partner must be experienced, accustomed to better-class work, and preferably between 30 and 40.
21. **WEST OF ENGLAND**.—COUNTRY TOWN. PRACTICE is good-class residential and consulting or established many years and now for disposal owing to vendor's retirement. Gross cash receipts about £1,200 p.a. Fees 7/6, 10/6, upwards. Suitable house available. Premium 2 years' purchase. Successor should hold M.D. or M.R.C.P.
22. **INLAND SPA**.—A ONE-THIRD SHARE is offered in well-established good-class practice producing approximately £2,700 p.a. Small panel. Average fees 7/6. Suitable house available on rental. Incoming partner should be about 30, experienced in midwifery and surgery to deal with Works' accidents. No major surgery. Premium 1½ years' purchase.
23. **DEATH VACANCY**.—BORDERS OF CAMBS. AND NORFOLK. Old established country PRACTICE producing between £1,250 and £1,300 p.a. including panel of about 800. Good house in nearly an acre of garden with professional accommodation, etc., electric light. Premium 1½ years' purchase, or near offer.
24. **COUNTRY PRACTICE WITHIN 30 MILES OF**.—Average gross cash receipts approximately £1,000 p.a., of which £533 p.a. is from panel. Scope for increase. Appointments worth about £50 p.a. Very low expenses. Good house in an acre of ground with 2 reception, 6 bedrooms, etc. Freehold for sale or might be rented. Premium 2 years' purchase.
25. **WITHIN 130 MILES NORTH OF LONDON**.—COUNTRY TOWN. Old-established chiefly non-panel better class PRACTICE averaging over £2,000 p.a. Fees 5/- to 21/-. Good house with ample accommodation. Premium 2 years' purchase.
26. **COUNTRY TOWN WITHIN 50 MILES OF LONDON**.—A ONE-FIFTH SHARE (after short preliminary assistantship) is offered in well-established practice producing nearly £5,400 p.a. with large panel. Suitable house on rental. Premium 2 years' purchase.
27. **NORTH LONDON**.—Well-established PRACTICE producing nearly £2,000 p.a. including panel and appointments. Suitable house available.
28. **SOUTH DEVON**.—COAST TOWN. Well-established PRACTICE producing last year over £1,000 (this year at rate of about £1,200 p.a.). Freehold house with 2 reception, 6 bedrooms, etc., for sale or might rent. Premium 1½ years' purchase.
29. **SOUTH-WEST COUNTY**.—A ONE-SIXTH SHARE is offered in old-established Practice producing nearly £7,000 p.a. Incoming partner must have made a special study of medicine and preferably hold the M.R.C.P. or have held a medical registrarship. Short preliminary assistantship. Suitable house available. Premium 2 years' purchase.
30. **SOUTH WELSH COAST**.—PARTNERSHIP. A ONE-HALF SHARE in old-established Practice producing over £3,000 p.a. Large panel. Very good house. Freehold for sale. Premium 2 years' purchase.
31. **NEAR BIRMINGHAM**.—A ONE-THIRD SHARE (after preliminary assistantship) is offered in sound steadily increasing mixed-class Practice producing £3,700 p.a. Panel of nearly 5,000. Premium 2 years' purchase.
32. **PARTNERSHIP**.—A TWO-FIFTHS SHARE, with increase to one-half later, is offered in old-established good country Practice within about 70 miles of London. Gross cash receipts for last 12 months approximately £5,500 p.a., including large panel. Moderate expenses. Very nice house with ample accommodation and all modern conveniences. Freehold for sale or might be rented. Premium 2 years' purchase.
33. **NORTH WALES**.—(Welsh not essential).—Old-established unopposed country PRACTICE in very pleasant district averaging for past 3 years approximately £2,000 p.a., of which over £600 p.a. is from panel and about £285 from appointments and clubs. Very convenient house in excellent repair, with electric light, garage, etc. Price of freehold, £1,500. Premium £3,600. Partnership introduction will be given.
34. **SURREY**.—DEVELOPING TOWN. Increasing PRACTICE producing for last year £655 and believed to offer considerable scope. Panel of about 450. Well-built semi-detached freehold house with 6 bedrooms, etc., or smaller house available if wished. Premium 1½ years' purchase.
35. **SOUTH-WEST OF ENGLAND**.—COUNTRY TOWN. A ONE-HALF SHARE is offered in old-established Practice producing over £1,400 p.a. but believed to be capable of considerable increase with the aid of an energetic partner. Panel of about 1,100 patients. Very good house with 2 reception, 4 bedrooms, etc., and all modern conveniences. Garden of about 1 acre. Premium for share and house, £2,500.
36. **NORTHERN OUTSKIRTS OF LONDON**.—PARTNERSHIP. A NINE-TWENTIETHS share (after preliminary assistantship) is offered in well-established Practice. Receipts for last year stated to be £2,162 p.a. Panel of 1,900 patients, and house with 2 reception, 3 bedrooms.
37. **NORTH LONDON**.—Old established PRACTICE producing for past two years about £2,100 with 2 reception, 4 bedrooms, small garden. Premium 2 years' purchase.
38. **SCOTLAND**.—UNIVERSITY CITY. Old-established non-dispensing PRACTICE producing about £820 p.a., including £540 from Panel and £280 from appointments. Suitable house, 2 reception, 6 bedrooms, etc. Freehold for sale on mortgage. Premium 1½ years' purchase or near offer.
39. **LONDON**.—Residential district. Long-established good general class PRACTICE producing over £3,000 p.a., with a full panel. Good house with ample accommodation, garden and garage. Freehold for sale or might be rented. A good introduction will be given.
40. **SOUTH COAST SEAPORT**.—Old-established mixed-class PRACTICE producing for past year over £3,000. Panel about 1,600. Various appointments. Well situated modern house, 3 reception, 5 bedrooms. Central surgery rented at £60 p.a., part sublet. Premium 2 years' purchase.
41. **SOUTH COAST**.—FAVOURITE TOWN. Old-established PRACTICE producing over £1,700 p.a. Panel of about 1,500. Appointments about £100 p.a. Scope for surgery. Prospect of hospital appointment. Low expenses. Suitable house with garden and garage on lease. Premium 2 years' purchase, to include book debts and drugs.
42. **GLOS**.—Sound old-established PRACTICE in beautiful country district averaging for past 4 years about £1,300 p.a. Panel over 1,100. Appointments about £80 p.a. Good house in own grounds. Freehold for sale. Premium 2 years' purchase.
43. **LANCS**.—SEASIDE RESIDENTIAL TOWN.—Easily worked, non-dispensing PRACTICE producing about £1,000 p.a., including £600 from panel of about 325. Low expenses. Suitable house available with consulting and waiting rooms, 2 reception, 3 bedrooms, maid's room, etc. Large garden. Garage. For sale or can be rented. Premium 1½ years' purchase.

The Agency has made arrangements for special facilities, on very favourable terms, to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application.

BRITISH MEDICAL ASSOCIATION

TAVISTOCK SQUARE

TRADITIONAL LONDON

THE 'BOAR'S HEAD',
EASTCHEAP, about 1730

Mention of this famous tavern, with its associations of Dame Quickly and Falstaff, has been traced back to 1537. After the Fire it was rebuilt and it survived until 1831. The sign, a boar's head, with the date 1668 and the initials of the landlord, are preserved in the Guildhall Museum.

London Hospital Catgut has no less finer traditions behind its development to a leading place in the esteem of Surgeons the world over. It is a product of scientific research, made throughout at the London Hospital under licence of the Ministry of Health.

HENRY KIMPTON'S PUBLICATIONSUP-TO-DATENEW THIRD EDITIONTHIS DAY**TEXTBOOK OF PATHOLOGY**

By WILLIAM BOYD, M.D., M.R.C.P.(Edin.), F.R.C.P.(Lond.).

THIRD EDITION, THOROUGHLY REVISED.

Royal Octavo, 1,064 pages, with 459 Engravings and 16 Coloured Plates.

Cloth.

Price 45s. net.

Much new material and many new pictures have been added to this edition.

NEW (THIRD) EDITIONTHIS DAY**AN INTRODUCTION TO CLINICAL PERIMETRY**

By H. M. TRAQUAIR, M.D., F.R.C.S.(Edin.).

THIRD EDITION, REVISED AND ENLARGED.

Demy Quarto, XV + 320 pages, with 227 Illustrations and 3 Coloured Plates.

Cloth.

Price 30s. net. (Postage 9d.)

"A work which has already won for itself the place of a standard work on the subject."—*The Lancet*."By his painstaking and accurate investigations on the pathology of the visual fields, Dr. H. M. Traquair has put the whole of English-speaking ophthalmology into his debt."—*British Medical Journal*.NEW (FIFTH) EDITIONJUST OUT**OPERATIVE GYNECOLOGY**

By HARRY STURGEON CROSSEN, M.D., and ROBERT JAMES CROSSEN, M.D.

FIFTH EDITION, ENTIRELY REVISED AND RESET.

Large Octavo, 1,076 pages, with 1,264 Illustrations, including 3 Coloured Plates.

Cloth.

Price 52s. 6d. net.

The six years since the last edition of this work constitute a period of unusual activity in searching out the fundamentals of gynecologic physiology and structure and in applying such knowledge to the cure of diseased conditions. This intensive study has extended also to our therapeutic resources giving a much better understanding of their possibilities. This new edition has been extensively rearranged and rewritten to cover this new knowledge. About 200 new illustrations have been added.

NEW BOOKJUST READY**THEORETICAL PRINCIPLES OF ROENTGEN THERAPY**

Edited by ERNST A. POHLE, M.D., Ph.D., F.A.C.R.

Royal Octavo, 271 pages, with 132 Engravings.

Cloth.

Price 21s. net. (Postage 6d.)

This book gives the basic facts of the physics of roentgen rays, the function and construction of the apparatus, dosimetry and the reaction of normal and diseased tissue to irradiation. It summarises what we know concerning roentgen therapy and supplies us with the answers to the innumerable questions regarding the apparatus, its operation and its possibilities. It gives the facts in radiobiology and pathology and the essential knowledge of how to protect the patient and the operator.

NEW BOOKJUST READY**CLINICAL ROENTGEN THERAPY**

Edited by ERNST A. POHLE, M.D., Ph.D., F.A.C.R.

Royal Octavo, 319 pages, with 199 Engravings and a Coloured Plate.

Cloth.

Price 45s. net.

The purpose of this volume is entirely a practical one: it is intended to offer the radiologist a guide in the treatment of conditions amenable to irradiation. Methods are described by each contributor which have proved valuable and safe in his experience. Each contributor is a recognised authority in his particular field.

NEW (SECOND) EDITIONJUST READY**EXTERNAL DISEASES OF THE EYE**

By DONALD T. ATKINSON, M.D.

SECOND EDITION, REVISED AND ENLARGED.

Royal Octavo, 718 pages, with 494 Engravings.

Cloth.

Price 36s. net. (Postage 8d.)

In preparing the second edition of this work the author has included descriptions of those important innovations in ophthalmic science of most recent origin. Among them are those dealing with slit-lamp microscopic and orthoptic training which will be found unusually helpful. Allergic ocular manifestations are also considered and many other accessions of a like nature enhance the value of the work.

NEW (EIGHTH) EDITIONREADY NOW**PHYSIOLOGY IN MODERN MEDICINE**

By the late J. J. R. MACLEOD, M.B.

Edited by PHILIP BARD

Professor of Physiology, Johns Hopkins University School of Medicine.

EIGHTH EDITION, REVISED AND REWRITTEN.

Royal Octavo, 1,036 pages, with 355 Illustrations.

Cloth.

Price 36s. net. (Postage 9d.)

In this new edition the present editor has followed a practice adopted by Prof. Macleod. Each major division is the work of a writer who is actively engaged in the study of the subject he treats. The greater part of the book has been entirely rewritten.

Special Commissioner Appointed for the purpose by the Council.

Complete Catalogue sent free on request.

LONDON: 136, GOWER STREET, W.C.1

RELIEF OF ECZEMA ★

We have on record many cases where persistent eczema, which had proved refractory, has yielded readily to Sphagnol Peat Ointment. It is commonly known that difficulty in obtaining rapid healing of eczematous conditions is often due to interference by the patient, provoked by the intensive irritation. Particularly is this so with children. Sphagnol Ointment soothes from the first application, giving instant

relief from itching. At the same time, the healing peat distillates which it contains promote the growth of clear, healthy skin.

In case you have had no personal experience of Sphagnol, we shall be pleased to send you a clinical size sample for testing if you will write to Peat Products (Sphagnol) Ltd., Dept. B.M.J.I., 21, Bush Lane, London, E.C.4.

Reader in Industrial Physiology, London School of Hygiene and Tropical Medicine.

They call it "the doctor's car"

The Wolseley 14/56 h.p. is particularly suitable for the work a doctor has to do, take for instance :—

EASY STARTING—In the Wolseley 14/56 h.p. a thermostatically-controlled water system does away with warming up delays and sluggish pulling. A 12-volt electric system and twin batteries ensure ample starting energy.

ROOMINESS—Quick and easy exit, through wide doors, fresh air renewal every 60 seconds and anatomically correct seating mean lack of fatigue on even the longest day.

NIGHTWORK—Powerful headlamps, twin fog lamps, stop and reversing lamps and duplex screen wipers lessen the strain of dark and rainy nights.

ECONOMY—24 to 28 miles per gallon is good for a "14," Wolseley stabilised production policy lowers depreciation.

QUIET—Body, door and floor are completely insulated from noise—the interior from fumes.

APPEARANCE—The Wolseley 14/56, either as a Saloon or in its Salon de Ville form, is a distinguished, handsome car—very indicative of the standing of its owner.

The price of the 14/56 h.p. Saloon is from £260—the Salon de Ville £325. 18/50 h.p. are from £280. Super Sixes from £350, and the 12/43 h.p. from £245.

And note that the Wolseley 14/56 develops 56 b.h.p.—well above the average and the highest output of any car paying 10 gns. tax.

Belts by Roussel bring *health* as well as *beauty*

Women will always seek to improve their figures, according to the fashionable line of the moment. How fortunate, then, when they can do so with a belt that is beneficial to health!

The special Roussel elastic weave, that allows variations in tension over different parts of a belt enables J. Roussel to model a belt for every individual case. Surgeons and doctors can agree to their patients wearing a Belt by J. Roussel

knowing that with the "varied tensions" feature, it can be made to exact measure and to extend pressure or support only where it is needed.

If you would like to know more about the Roussel Belt may we send you a copy of our beautifully illustrated Catalogue?

PISTAN MUD COMPRESS for CHRONIC RHEUMATISM

Radio-active sulphuric Mud from the world-famous
springs of Pistan Spa; made in poultice form to fit any
part of the body, it may be used over and over again
by simply dipping the compress in hot water before
its application. Indicated in practically all kinds of
chronic rheumatism, peri-articular, articular, muscular,
or neuro-fibrositis. Also a great value in the treat-
ment of sprained joints (especially for absorption of
exudates) and of climacteric arthritis. Can be used as
an abdominal or liver pack.

ALUZYME • NON-AUTOLYSED YEAST

Professional samples, descriptive
matter and prices on request.

ALUZYME PRODUCTS,
PARK ROYAL ROAD, LONDON, N.W.10.

BEST FOR ORAL ADMINISTRATION OF NUCLEIN AND THE ENTIRE B VITAMIN COMPLEX

Plain Brewers' Yeast stabilised by low temperature dehydration. This leaves the cells intact; Aluzyme contains 95% of vital cells and therefore provides all the essential constituents of yeast in the fully active state of living substance. Officially certified Vitamin potencies: B₁: 1140 Internat. Units per ounce. B₂ Complex: Maximum for Dried Yeast. Sulphur content, 0.47%; Nuclein, 0.4%. Glutathione reaction, brilliant magenta. Flavin Fluorescence test, medium blue. Its therapeutic value in B avitaminosis, furunculosis and the Anaemias is apparent from these particulars.

FORD V-8 "22"

ANY WAY YOU LOOK AT IT The Ford V-8 "22" is still the best proposition you can find at anything like its price! Power, refinement of performance, comfort, equipment, finish, dependability, it is a car of which you can be thoroughly proud, with which you will be handsomely satisfied from the moment it's yours!

Overseas Delivery of any Ford Car can be arranged by any Ford Dealer, or through our London Showrooms.

Features:

The eight-cylinder engine develops over 60 b.h.p., though taxed at only £16 10s. per annum in Great Britain • It is an extremely economical car to run, alike on fuel, lubricants and tyres • There is liberal luggage accommodation, under lock and key, and the spare wheel is completely enclosed • All passengers ride between the axles, enjoying maximum comfort • Instrument-panel is right in front of the driver • The adjustable front seat is mounted on tubular steel supports. The rear seat has a folding central arm-rest • Safety glass is fitted all round. Sun-visors, clock, cigar-lighter, roof-light, direction-indicators and dual windscreen-wipers are standard equipment.

**Do you like
being lazy ?**

Most of us seem to prefer our tobacco READY RUBBED—it saves trouble. That's why we now pack even single ounces of the Ready Rubbed in airtight tins—as shown. But if you prefer your tobacco left in the Original form, you can always get it—in ounce packets. Both cost the same—a convenient shilling an ounce. And if you like to buy a couple of ounces at a time, you can get either sort in the special vacuum tins. Anyway, just try this Cut Golden Bar—it's stood the test of 40 years.

W. D. & H. O. Wills.

Improved Lubrication Therapy

THE advantages of lubrication therapy over the more or less drastic depuratives are too well known to require reiteration. Physicians have, however, experienced the disadvantages which ordinary medicinal paraffin possesses—viz., uncleanly in use, unpleasant insipidity and risk of "leakage."

"Cristolax" brings a new efficiency to the technique of lubrication therapy. 50 per cent. of liquid paraffin of the highest purity and optimum viscosity is so skilfully incorporated in "Wander" Dry Malt Extract that every vestige of disagreeable oiliness is completely eliminated.

"Cristolax" is so pleasant to the taste that it can be prescribed with entire confidence for the most fastidious patient. Its digestive and nutritive value render it of special service in constipation associated with defective assimilation, dyspepsia, and general debility.

EXTRA - CELLULAR NUTRIMENT FOR MORE COMPLETE ASSIMILATION IN INFANT DIETARY

By the Libby process of Homogenization the tough walls of food cells are burst and broken up into fine particles. The nutriment thus being extra-cellular is therefore rendered immediately accessible to the gastric enzymes and thoroughly assimilable without digestive strain.

The break up of the fibrous tissue has the added advantage of providing smooth non-irritating bulk and obviating the incidence of intestinal disorders—particularly diarrhoea—primarily due to the passing of food cells through the digestive tract with their tough outer walls intact.

Libby's Homogenized Vegetable Foods are eminently suitable for very young and weak digestions and can be prescribed with confidence in very early cases of nutritional anaemia. They are prepared in six scientifically formulated combinations of Cereal, Vegetables and Fruit. These can be prescribed as needed to provide the necessary balance of Vitamins, Minerals and other essentials.

Samples together with clinical data and Laboratory reports will be gladly supplied upon request to Messrs. Libby, McNeill & Libby Ltd., London, E.C.3.

MILTON

★ **DETERGENT**
PENETRATIVE
GERMICIDAL
OSMOTIC
NON-TOXIC
LIQUEFACTIVE
REGENERATIVE

★ **Detergent** Milton dissolves necrotic animal tissue and decomposes (by oxidation) organic toxins, the odours of which are instantly destroyed.

It is particularly to be recommended as a deodorant for use in inoperable cancer, fetid breath, ozoena and in all cases generally of odour due to organic decomposition.

The qualities of Milton and its superiority over other "hypochlorite" antiseptics—e.g., Dakin's fluid and Liq. sod. chlorinatae—have been clearly demonstrated by special laboratory researches, the results of which have been amply confirmed in practical use. Copies of these reports and a sample of Milton will be forwarded to any medical practitioner on request.

Milton is supplied at a standard strength ready for immediate use, and is stable. It is safe for either external or internal application.

MILTON PROPRIETARY LIMITED,
10/12, BREWERY ROAD, LONDON, N.7

CAPROKOL In Urinary Infections

Caprokol therapy possesses advantages over other forms of treatment of infections of the urinary tract inasmuch as it is equally active in either an acid or alkaline urine. Furthermore, its administration is not contra-indicated in cases of renal damage; indeed, it is adopted on account of its real value in relieving the painful symptoms which often accompany urinary infections, particularly in the elderly patient.

Cap/109

Doctors who have tested them, believe in Baxter's Intravenous Solutions in Vacoliters.

1. They are made from protein-free water—hence of constant pH value.
2. Baxter solutions are non-pyrogenic; free from any anaphylactic reactions. One of England's leading surgeons has said in a recently published article "they never produce fever or thrombosis."
3. All solutions are biologically tested after sterilisation. The vacuum sealed Vacoliter is made of special glass, treated by a special process, which ensures the solutions remaining sterile indefinitely. To confirm this, master samples are kept which are periodically re-tested by independent clinical authorities of the highest ethical standing.
4. Instantly available. From the stock room to the patient's vein is a matter of moments. Administration is as simple at the scene of an accident as at the patient's bedside. No special equipment is required.
5. There are many ways in which intravenous therapy helps to make a patient a better "risk." Because of their qualities, Baxter solutions will ensure the maximum results in this direction.

Intravenous solutions are Baxter's entire business. Four laboratories produce annually more than 3 million litres. Many leading institutions, well equipped to make their own up to earlier standards, have signed contracts standardising Baxter solutions each year. Fewer hospitals continue to make their own solutions.

OVALTINE

IN PREGNANCY

THE physiological drain of calcium, phosphorus, vitamins and other important food elements calls for replacement during pregnancy. Composed of milk, eggs and malt, 'Ovaltine' supplies these essentials in a delightful form which does not overtax the unstable maternal digestion. A cup of 'Ovaltine' on arising, during the early months, is often effective in controlling sickness and has a food value greater than three eggs.

IN LACTATION

To maintain lactation to the eighth month is an ideal not often realized under modern conditions of life. Ample evidence is available to show that 'Ovaltine' has a definite action in increasing the flow and enriching the quality of the milk. It has, moreover, a beneficial effect on the health of mother and child. The flavour is so agreeable that it can be taken for prolonged periods without any distaste arising.

COLLOIDAL... ASSIMILABLE... PALATABLE

Ovoferrin Brand Colloidal Iron Tonic, the palatable blood builder, is stainless, odourless, non-astringent. It is iron in its most minute, most useful colloidal subdivision. Ovoferrin does not constipate; it does not affect the teeth or stomach; rather, it stimulates the jaded appetite and often aids in intestinal peristalsis. Many physicians have found it to be the only preparation simple, agreeable and effective enough for long term iron feeding. Ovoferrin contains no flavouring or sugar; it is economical to use and an excellent vehicle. Write for free professional sample.

Diphtheria

GLOBULIN *Lederle* MODIFIED

ANTITOXIN

THE GLOBULIN-MODIFIED *Lederle* technique, embodying the principle of peptic digestion, is the only practical procedure which permits such a high degree of concentration of antitoxin and reduction in the amount of troublesome proteins—the cause of serum reactions.

That is why Globulin Modified Antitoxins *Lederle* represent

- a reduction in the expected incidence and severity of serum disease;
- less inconvenience to the patient;
- a greater ease of administration;
- a greater potency per c.c.

DIPHTHERIA ANTITOXIN *Lederle* as prepared by the Globulin Modified Technique contains 6,000 to 7,000 units per c.c., except in the lower unitages where the volume is adjusted to facilitate ease of handling. A concentration which we believe has never been previously attained with commercially available antitoxins.

Since Diphtheria Antitoxin absorbs circulating toxins and checks the further spread of the toxæmia, prognosis is largely dictated by the promptness by which adequate dosage is injected and the route by which it is given.

The improved and refined *Lederle* product permits of the administration of large dosage in small bulk by the intravenous route without the fear of untoward reactions.

Each tablet contains
5 mg. β -Phenylisopropylamine Sulphate
(Isomyn Sulphate)

In Asthenic States

POSSIBLY the most interesting clinical application of 'Benzedrine' Brand Tablets (β -Phenylisopropylamine Sulphate) is with that ill-defined group of non-psychopathic cases with persistent functional symptoms of apathy, weakness, exhaustion, and undue fatigability.

When these patients fail to respond to rest and the usual methods of treatment, 'Benzedrine' Brand Tablets are often particularly helpful.

A sample of 'Benzedrine' Brand Tablets, together with the most recent literature on the treatment of such asthenic conditions, will be sent to any interested physician on request.

"From the evidence which has so far accumulated benzedrine does not appear to be toxic in usual doses nor does it seem to be habit forming."

—JOURN. AMER. MED. ASSOC., 109: 549, 1937.

'BENZEDRINE' BRAND TABLETS

In Rheumatic Conditions

Rx

COLLOSOL SULPHUR $\bar{3}$ viii
Sig. $\bar{3}$ i thrice daily, after meals,
in a wineglassful of water.

Alternate weekly with
COLLOSOL IODINE $\bar{3}$ x
Sig. $\bar{3}$ i or $\bar{3}$ ii thrice daily, after meals,
in a wineglassful of water.

As auxiliary measures
COLLOSOL SULPHUR BATHS
 $\bar{3}$ iv mitte xii
Sig. one bath every fourth day.

COLLOSOL IODINE OIL $\bar{3}$ i
Well rubbed in every night.

The success of Collosol Iodine and Collosol Sulphur used separately indicated that as both drugs fill an important place in the treatment of infective and other conditions such as Early Rheumatoid Arthritis, Muscular Rheumatism, Fibrositis, Sciatica,

etc., by alternating the treatment a valuable addition to the armamentarium of the practitioner would be afforded. Actual clinical results prove that the combination does produce the results expected from theoretical considerations.

COLLOSOL IODINE is unaccompanied by the disadvantages usually associated with iodine treatment: It remains stable in the gastric juices and is absorbed in the tissues. COLLOSOL SULPHUR, unlike the ordinary pharmaceutical preparations of sulphur, readily combines with proteins in the intestinal tract and is entirely absorbed.

Special monograph upon application.

SEX HORMONE PREPARATIONS

GONAD STIMULATING HORMONES

ANTOSTAB

Prepared from pregnant mares' serum and contains the follicle stimulating hormone. Excellent clinical results have been obtained in the treatment of Amenorrhoea either alone or in conjunction with Physostab. (*Brit. Med. Jnl.* 1937, ii, 394) Supplied in boxes containing ampoules of 100 mouse units together with ampoules containing 1 c.c. of 0.90% Sodium Chloride Solution as a solvent. Single ampoules and boxes of 6 ampoules.

PHYSOSTAB

Prepared from human pregnancy urine and contains the luteinizing hormone. Of especial value during the second half of the menstrual cycle when it stimulates the production of corpora lutea. Excellent clinical results have been obtained in the treatment of metrorrhagia, undescended testicles and dystrophia adiposo-genitalis. Supplied in boxes containing ampoules of 100 mouse units, together with ampoules containing 1 c.c. of 0.90% Sodium Chloride Solution as a solvent for Physostab. Single ampoules and boxes of six ampoules.

OVARIAN HORMONES

OVOSTAB

An oily solution of ovarian hormone for intramuscular injection in the treatment of Amenorrhoea, the Menopause, Chronic Mastitis and cases of Ovarian Deficiency. Supplied in 1.1 c.c. ampoules containing 2,000, 10,000 and 50,000 International Benzoate Units per c.c. Single ampoules and boxes of six ampoules. Ovostab tablets (Oestrone) are available for oral use. 1,000 and 10,000 International Units per tablet. Bottles of 25.

LUTEOSTAB

An oily solution of the corpus luteum hormone for use in conjunction with Ovostab in treating Amenorrhoea and for the treatment of Abortion, Metrorrhagia and cases of Corpus Luteum Deficiency. Supplied in 1.1 c.c. ampoules containing 2 rabbit units per c.c. Single ampoules and boxes of six ampoules.

MENINGOCOCCUS ANTITOXIN

Meningococcus Antitoxin has been developed by immunizing horses with the soluble exotoxins. The antitoxic property of the serum is demonstrated by its ability to neutralize toxin, as shown by intradermal injection in susceptible human beings.

A number of cases of cerebro-spinal fever, treated with Ferry's Meningococcus Antitoxin in certain hospitals of the London County Council at the request of the Ministry of Health, were reported in "The Lancet," April 13, 1935.

Several clinical considerations are advanced to strengthen the suggestion that the antitoxin is more potent therapeutically than the usual polyvalent serum, at least for Group I (types I and III) infections.

Further particulars will be supplied on request to:

Meningococcus Antitoxin (P. D. & Co.) is supplied in 30 c.c. vials representing 10,000 units of antitoxin.

Cadbury's have perfected a
SPECIAL CHOCOLATE
which is Sugar Free and
therefore a suitable addition to
the dietary of diabetics

This chocolate is extremely palatable, and because Cadburys have unlimited facilities for laboratory research and the subsequent manufacture and marketing of such a product it sells at a very low price. Further details and analysis with a sample of this Special Chocolate will be gladly forwarded to anyone interested. Please write to Cadburys Laboratories, Bournville.

CADBURY BROS. BOURNVILLE ENGLAND

ANAHÆMIN B.D.H.

In the treatment of pernicious anæmia

The following clinical report upon a very severe case of pernicious anæmia for the treatment of which it was deemed advisable to adopt a scheme of dosage on a higher scale than is necessary in average cases is of unusual interest.

Female 68 years . . . pallor, lassitude, anorexia, nausea, vomiting, giddiness, weakness and numbness of the legs. Sleeping badly. Losing weight.

On admission T.100.2 P.100 R.23 B.P.110/70

Treatment 31.8.37, 1.9.37, 3.9.37, 5.9.37 and 10.9.37 2 c.c. of Anahæmin, then twice weekly

Blood counts 1.9.37 Hb. 25% r.b.c. = 1.2 millions per c.mm. C.I. = 1.0
20.9.37 (21st day of treatment) Hb. 65% r.b.c. = 3.6 millions per c.mm.
C.I. = 0.9

Summary In 7 days, after 8 c.c. of Anahæmin, hæmoglobin rose from 25% to 45%.
In 14 days, after 10 c.c. of Anahæmin, Hb. rose to 55% and the red cells in the smear showed very little abnormality.

THE BRITISH DRUG HOUSES LTD. LONDON N.1

Disease-emaciation

"EVERY medical practitioner knows how difficult it is to nourish a patient suffering from disease-emaciation. . . . Do we not all recognise the fact that the starving tissues are fed, not by the food swallowed by the patient, but by the amount of nutrient matter absorbed by the gastric and intestinal mucous membrane? If we could ensure the absorption of nutriment into the blood, the problem of nutrition in disease would be reduced to a matter of mere chemistry and mechanical feeding. . . . Judging from clinical results, 'Sanatogen' appears in many cases to possess some power of ready absorbability, without which the richest foodstuff represents simply so much foreign matter in the stomach and intestines. . . . My own experience of 'Sanatogen'. . . is that it stays the diarrhoea—ten or twelve motions a day are thereby reduced to one or two; it stops vomiting, and it improves general conditions and causes the patient to put on flesh."

"NUTRITION IN WASTING DISEASES OF CHILDREN AND ADULTS"
(*Medical Press and Circular*)

"THIS condition, which results from imperfect digestive or absorptive power, or which may follow stomatitis, pyloric stenosis, deformity of the tongue or palate, tuberculosis or syphilis, is most frequently associated with improper feeding. Fats in such cases are not well tolerated, but the contrary is true with respect to proteids. . . . The use of 'Sanatogen', in these cases, proved so satisfactory that we have been encouraged to try it in other cases of infantile atrophy, and have had almost equally pleasing results in a number of patients suffering from this condition. It is quite apparent that 'Sanatogen' has considerable power in influencing nutrition. . . ."

"INFANTILE ATROPHY"
(*Practitioner*)

"I HAVE before me the records of forty cases fed with 'Sanatogen'. They show, what was obvious to myself and the nurses when watching the cases, that these patients wasted less during the acute stage, and picked up more rapidly during the convalescent stage, than patients who did not have 'Sanatogen'. This fact, indeed, was soon recognised by the ward sister, without my having in any way drawn her attention to it. . . . I am firmly convinced that it is a most valuable food for the typhoid patient."

"THE TREATMENT OF TYPHOID FEVER"
(*Medical Times*)

SANATOGEN

Sold by all chemists
price 2/3 to 19/9

DOSAGE: For children and adults two teaspoonfuls three times daily, or according to circumstances. For infants $\frac{1}{2}$ teaspoonful added to each bottle feed.

ONE-HALF *the dosage*
the quantity of drug to be eliminated

Administered orally, rectally or, in emergencies, intravenously, Nembutal exerts an extremely rapid but brief hypnotic and a pronounced sedative action from a dosage only about one-half that required with most other powerful barbiturates. This small dosage reduces the recovery period also by about one-half and, by lessening the amount of the drug to be eliminated, makes Nembutal, clinically, one of the safest of the barbiturates. ● Safety, rapidity and brevity of action recommend Nembutal for use not only as a pre-anæsthetic sedative in major and minor surgery, but also in the treatment of insomnia, hysteria, sea-sickness, nausea from any cause, eclampsia,

delirium tremens, convulsions from strychnine or other poisoning and in obstetrics—with or without morphine and scopolamine. Nembutal has also been used with much success as a supplement to morphine in controlling the pain of early cancer. ● Nembutal is available through pharmacies in a wide variety of forms, the most widely employed of which are the $\frac{1}{2}$ -grain and

$\frac{1}{2}$ -grain capsule for oral use. Literature and a trial sample of Nembutal $\frac{1}{2}$ -grain Capsules will be sent upon request. The coupon is for your convenience.

The Lister Institute

OF PREVENTIVE MEDICINE

Elstree, Herts.

Staphylococcus Toxoid

Staphylococcus aureus is responsible for a great variety of inflammatory conditions that are frequently met with in medical practice.

Beneficial results have been obtained by means of this immunising agent in the treatment of patients who had suffered from a chronic staphylococcal infection and who had failed to respond satisfactorily to vaccine therapy and other recognized therapeutic measures.

Staphylococcus Vaccine - Toxoid

This preparation consists of a mixture of staphylococcus vaccine and staphylococcus toxoid in suitable proportions. In view of the beneficial results obtained from the use of staphylococcus toxoid alone, and the recognised value of staphylococcus vaccines it is reasonable to hope that the combined remedy will prove to be of value in cases which have not responded satisfactorily to any form of treatment.

Full details regarding the mode of administration and the scale of doses employed are enclosed in each package, and may also be obtained from the

THE PHYSICAL BASIS OF "BILIOUSNESS" AND "WIND ROUND THE HEART"*

BY

SIR ARTHUR HURST, D.M., F.R.C.P.

Senior Physician to Guy's Hospital

"BILIOUSNESS" OR A "TOUCH OF LIVER"

Among the commonest conditions of which patients complain is a "touch of liver" or a "bilious attack." As neither is mentioned in most textbooks of medicine, it is natural that a recently qualified doctor should conclude that there is no such thing and should be driven to explain to the sufferer that what he puts down to his liver is really a disorder of his stomach, his bowels, or his nerves. But the patient remains unconvinced, and when next he wakes up with a dull headache, a dirty tongue, no appetite for breakfast, and the conviction that life is not worth living, he will tell his wife that his bad temper is due to his liver, and the doctor be damned. It is a curious fact that there is no equivalent in French or German for the word "liverish" or a "touch of liver," though a bad-tempered Frenchman is said to be "un bilieux." There is also no record of the word "liverish" being used in England before the first quarter of the nineteenth century, and I am inclined to think that it was introduced by soldiers and civilians who came home to nurse their damaged livers in Cheltenham and Bath, as it was in India that the frequency of hepatic abscess first led Army surgeons to recognize the premonitory symptoms of a disordered liver.

I believe that the patient who says he is liverish is often correct, and that functional disorders of the liver are actually far more common than organic diseases. The liver has more ways in which it can be attacked than any other organ. Poisons absorbed from the stomach, intestines, gall-bladder, and spleen reach it in the blood of the portal vein; poisons and organisms in the systemic circulation are conveyed to it by the hepatic artery; infections may ascend the bile ducts from the duodenum, especially in the presence of achlorhydria; and infection may be carried by lymphatics from the wall of the gall-bladder.

Alcohol is the commonest cause of liverishness, but there are many others. The intestinal toxæmia which results from the habitual abuse of purgatives, though never from untreated constipation, and all forms of food poisoning and intestinal infections, such as those with typhoid and various parenteric bacilli and with *Amoeba histolytica*, as well as such general infections as septicaemia and malaria, may injure the liver. With the exception of alcohol and amoebiasis they rarely produce enough damage to give rise to symptoms unless two or more are associated together. But an acute "liver attack" may occur in all these conditions as a result of indulgence in an amount of alcohol which formerly would have had no ill effect, and indiscretions in diet, fatigue, and excitement

are often contributory causes. A patient of mine, a man of 58, found it difficult to decide whether a bad liver attack was too high a price to pay for his sole pleasures in life, betting at race meetings and gambling at Monte Carlo, both of which invariably brought one on even if he drank no more alcohol than usual.

The liver is well provided with means for dealing with toxins and bacteria, but it is not always capable of destroying them when they arrive in excess. The hepatic cells are then damaged and their functional capacity is impaired. The damage in the early stages is not irreparable, and although microscopical examination would doubtless reveal the presence of structural changes, they are at first of a type from which complete recovery can take place. The ordinary clinical methods of physical examination do not give any safe guide to the diagnosis of these early stages of hepatic disorder, but fortunately in the laevulose test we have a means of recognizing them. Our experience of over a thousand cases at New Lodge Clinic in which the possibility of hepatic insufficiency required consideration has led us to regard it as a very reliable test of liver function. We now consider a combined one-hour and two-hour rise in the blood sugar of more than 25 mg. per 100 c.cm. after taking 50 grammes of laevulose as suspicious, and of more than 30 mg. as certain evidence of hepatic insufficiency.

Alcoholic Hepatosis

It is obvious that cirrhosis of the liver is only the last phase of a very long-standing disease, the early stages of which have passed unrecognized. As the condition is one of toxic degeneration rather than inflammation it is more suitably described as hepatosis than hepatitis. Whereas the death rate per million living from cirrhosis of the liver has fallen from 248 in 1902 and 185 in 1912 to 81 in 1922 and 50 in 1932, alcoholic hepatosis is quite common, especially among the well-to-do. The familiar symptoms of "the morning after the night before" are the symptoms of acute alcoholic hepatosis, and the laevulose test shows that definite hepatic insufficiency is present and disappears completely within a few days. Table I shows the results of the laevulose test in five healthy young men on the morning before a "night out" compared with the morning after. In each case there was a greater rise in blood sugar with the second test than with the first, which showed an actual fall in four instances. The rise was greatest in A and B, the only ones who felt any the worse for the experiment.

Habitual over-indulgence leads to a chronic alcoholic hepatosis, which is still capable of complete resolution even if it has been present for many months. It is only when it has continued without intermission for years that irreparable damage is done, but the nodular hyperplasia

Bilious Attacks and Migraine

What is called a bilious attack in a child is in most cases the equivalent of migraine in an adult. One or other parent is often a sufferer from migraine, and the child is likely to develop it when he grows up. The term "bilious attack" is apparently derived from a misinterpretation of the fact that it often terminates with bilious vomiting. There does, however, appear to be some obscure connexion between the liver and migraine in a proportion of cases in both children and adults (Hunt, 1933). We have never found any sign of hepatic insufficiency as shown by the laevulose test, and van den Bergh's test is negative both during and between the attacks. But when in the course of our investigations we aspirated a specimen of bile through Einhorn's tube after making the gall-bladder and bile ducts evacuate their contents by injecting magnesium sulphate into the duodenum, a number of adult patients asked to have the process repeated, as they felt clearer in their heads and altogether less "bilious" than they had done for months. In these cases the gall-bladder was often found to be tender, especially shortly before and during an attack. It is apparently the mechanical effect of unloading the liver of accumulated bile which has this unexpected result, as in every case the bile was quite normal and there was

diseases of the gall-bladder, and although there does not appear to be any special liability to cholelithiasis among the migrainous, it seems not improbable that a disordered liver may be one factor in the complicated pathogenesis of migraine.

"WIND ROUND THE HEART"

Aerophagy

There is no physical basis for the wind which troubles most people who complain about it; it is on their brains, and neither in their stomachs nor round their hearts. Nearly thirty years ago I described experiments which showed that the only adequate stimulus to the sensory nerves of the alimentary tract is tension on the fibres of its muscular coat (Hurst, 1911). A slight increase gives rise to the sensation of fullness and a greater rise to pain. The tension depends upon the postural tone of the muscle fibres and the volume of the contents of the segment concerned. A sensation of fullness and pain may result from increased tone of the muscles with no change in the contents, or upon increase in the volume of the contents with constant tone. The sensation of fullness or pain can be relieved when some or all of the contents consist of gas, which can be evacuated by belching from the stomach or as flatus from the colon. Everybody has had experience of gaining relief in these ways, and consequently the average person is inclined to ascribe a sensation of fullness in the stomach or colon to wind, although in most cases it is due to other causes. Success confirms his suspicion, but instead of accounting failure to a wrong diagnosis he assumes that wind is present but cannot be expelled. In his futile attempts to eructate he swallows air until enough is present in his stomach to be easily and loudly evacuated (Fig. 1). The relief which follows is partly psychological and partly due to the fall in intragastric tension. As the discomfort which initiated the aerophagy is often due to achalasia or spasm of the pyloric sphincter, the primary discomfort may be overcome, as the further rise in intragastric pressure resulting from the aerophagy may be sufficient to force the pylorus as well as the cardia (Fig. 1d). Sodium bicarbonate gives relief in precisely the same way as aerophagy: carbon dioxide is evolved

FIG. 1.—Drawings to illustrate the relief of intragastric tension by aerophagy

no evidence of coexisting cholecystitis or gall-stones. Such patients derive benefit from stimulation of biliary drainage by means of Epsom salts and olive oil. The former should be given in concentrated solution fasting every morning, the dose being the largest which can be taken without causing looseness, and a tablespoonful of the latter should be taken three times a day half an hour before meals.

A large proportion of sufferers from migraine know from experience that fatty food induces an attack, and among those who have not discovered this for themselves it is common to find that the exclusion of eggs, cream, fat meat, fried food, and chocolates helps to prevent migraine. It is interesting to observe that these are just the cholesterol-rich foods which frequently upset patients with

by the action of the acid gastric juice, and the increased tension in the stomach forces gas through the cardia and fluid through the pylorus. In both cases the patient brings up gas, and it is difficult to convince him that this is not the product of fermentation in his stomach. But owing to the inhibiting action of free acid on bacterial activity and the continuous passage of food into the duodenum fermentation cannot occur; we have found that even in complete achlorhydria very little gas is produced by fermentation unless pyloric obstruction is also present.

Neurotic patients may get so much satisfaction from belching wind with a resounding noise that they continue to swallow air, and the whole process is repeated again and again. Eventually attacks of aerophagy occur with-

caused by new-formed liver tissue may even then compensate for this more or less completely, although areas of complete necrosis are gradually replaced by fibrous tissue, the first stage of cirrhosis having at last developed.

Over-indulgence in alcohol is a very elastic term, what is excess for any given individual depending upon the vulnerability of his liver cells, which varies greatly in different people. It has nothing to do with his general reaction to the effects of alcohol, as alcoholic hepatitis is not often associated with alcoholic psychoses or peripheral neuritis. The premonitory symptoms of cirrhosis are mainly hepatic in origin, though chronic oesophagitis and, less frequently, chronic gastritis may contribute to them; but the latter is not necessarily present, a normal curve of acidity without any excess of mucus being often obtained with a fractional test meal.

Young men and girls who indulge in cocktails three or four times a week may develop alcoholic hepatitis. Their anxious parents are apt to ascribe their sallow complexions, loss of appetite, mental torpor, and irritability to incipient consumption or other serious disease, but the well-marked hepatic insufficiency disclosed by the laevulose test and the tender and often slightly enlarged liver reveal the true nature of their malady. Complete recovery with disappearance of liver tenderness and return to a normal response to the laevulose test quickly follows a period of rest with a light diet and abstinence from alcohol.

Table II gives some examples of the results of the laevulose test in alcoholic hepatitis before and after treatment. Patient No. 6 had drunk a bottle of champagne a day for twenty years, and was so ill that he was thought to be dying from some obscure abdominal complaint. His liver was large, hard, and very tender. After three months on a strict diet his liver was no longer palpable, and he returned home feeling perfectly fit and able to play tennis and golf for the first time for five years. No. 7 had been drinking from one to three bottles of whisky a day for over a year, and also recovered completely.

The tender liver often aches, and a man "with a liver" has generally a fairly accurate knowledge of its surface anatomy. He is never jaundiced, and latent jaundice, as shown by a positive indirect van den Bergh reaction, is uncommon; when present it disappears as rapidly as the abnormal response to the laevulose test.

In early cases, after a short period of strict treatment, it is only necessary to forbid alcohol in any form between meals, when it is rapidly absorbed and reaches the liver in a comparatively concentrated form. But in more advanced and chronic cases it is useless to advise anything short of complete and permanent abstinence. This advice is easier to follow than might be expected, as the patients are never dipsomaniacs and have no uncontrollable urge

TABLE II.—Laevulose Tolerance Test in Alcoholic Hepatitis Before and After Treatment

to drink. They drink for conviviality and because they like it or find it difficult to complete a business deal without celebrating it with a drink. A badly damaged liver is abnormally vulnerable to such toxins as alcohol, and even a small dose is poisonous. But more important is the psychological fact that with his first drink a man's judgment is impaired, and though he may have intended to take no more he will have a second and a third, and so on *ad infinitum*. He is only safe when teetotal.

Amoebic Hepatitis

In 1923 Lieutenant-Colonel Gordon Covell published in the *Guy's Hospital Reports* a paper in which he showed that amoebic dysentery was always accompanied by hepatic insufficiency as measured by the laevulose test, even in the complete absence of symptoms pointing to disorder of the liver. Since that time we have always performed the laevulose test in the many patients who, on returning home after long residence in the East, complain of general unfitness in the absence of any obvious organic disease. They look pale and sallow, though they are neither anaemic nor jaundiced and van den Bergh's reaction is generally negative. They have frequent liver attacks—headache with a dirty tongue, anorexia, discomfort in the region of the liver, and constipation or alternating constipation and diarrhoea. The liver is often slightly enlarged and tender, and the laevulose test shows that hepatic insufficiency is present. Though alcohol and various infections may have contributed to this result the condition is mainly due to a mild chronic form of amoebic hepatitis. The patient may have had definite attacks of dysentery, but more frequently he has had nothing else than an occasional attack of diarrhoea, and sometimes not even that, yet the caecum and ascending colon are often tender, and the appendix has generally been removed for "chronic appendicitis" without benefit. It is remarkable that this condition, which never leads to abscess formation, can persist for several years after returning to England and yet be amenable to treatment. It often remains unrecognized owing to too much reliance being placed on the presence of cysts of *Entamoeba histolytica* in the stools as essential evidence of the existence of amoebiasis.

Complete recovery follows a dozen injections of 1 gram of emetine. The patient not only loses his symptoms but the liver ceases to be palpable and the laevulose test

occurred when food was brought into his room persisted in a lesser degree after the disappearance of the associated emotion, presumably as a result of a conditioned reflex. The ulcer became much smaller, but after many

FIG. 3.—Man aged 76 with eventration of diaphragm caused by aortic stenosis secondary to esophageal ulcer.

FIG. 4.—Same case as Fig. 3 after taking opaque fluid whilst in horizontal position to show ulcer.

weeks it had not healed owing to the development of cicatricial narrowing, and eventually a gastrostomy was performed. This resulted in complete healing with disappearance of the occult blood from the stools. The cicatrization of the ulcer led to almost complete obstruc-

tion; this would probably have been overcome by gradual dilatation had he not developed a rapidly fatal attack of acute mania.

A similar condition of *aérogastrie bloquée* may result from dislocation of the cardia, which is generally caused by excess of gas in the neighbouring splenic flexure. The excess of gas escapes from the stomach when it can reach the pylorus on assuming the horizontal position. In the morning no excess is present, but with each meal the quantity increases until the afternoon, when the accumulation produces a rise of pressure sufficient to cause pain, the diaphragm at the same time being displaced into the thorax. Immediate relief follows the passage of a stomach tube. One patient with this condition had learnt to lie down at 3 p.m. every day when the pain was at its height (Figs. 5 and 6). In half an hour he was com-

FIG. 5.—Man aged 43 with eventration of diaphragm caused by aortic stenosis. Erect position.

fortable, as the gas had passed into his small intestine, and after another hour he evacuated some of it per anum, but enough remained in his splenic flexure to maintain the dislocation of his cardia. Permanent relief occurred only after he had evacuated the gas from his stomach by a tube at 3 p.m. every day for a week, so that no excess passed through his pylorus to collect in the colon.

FIG. 6.—Same case as Fig. 5 in horizontal position, with gas escaping into duodenum and disappearance of eventration.

(b) MEGACOLON AND AÉROCOLIE BLOQUÉE

Megacolon is the result of interference with the normal neuromuscular mechanism controlling the last stage of the act of defaecation, in which the passage of faeces from the pelvic colon into the rectum causes the latter to contract and the sphincter ani to relax. When owing to degeneration of Auerbach's plexus or other causes the sphincter does not relax (achalasia), faeces and gas are retained, and the rectum and especially the more thin-walled pelvic colon become progressively dilated (Hurst, 1934b). The pelvic colon finally forms a huge loop, which reaches the left and occasionally the right dome of the diaphragm. Megacolon is the commonest cause of eventration of the diaphragm. I have seen thirty-five cases in private practice—twenty-four in males and eleven in females, including four boys and one girl (so-called Hirschsprung's disease)—compared with two cases caused

out any preceding epigastric discomfort, the condition then having all the characteristics of a tic. The action, though originally serving a useful purpose, no longer does so; its repetition depends upon the subconscious gratification which it gives to the patient, who is able to restrain it by an effort of will, but after a short time gives way to an overwhelming impulse to continue, though often ashamed of his weakness.

Aerophagy can be cured by explaining the true cause of the "flatulence" in language suited to the patient's intelligence. He is instructed to make no voluntary effort to eructate, however much he may desire to do so. At the same time an attempt must be made to discover and relieve the primary cause of the discomfort which led to the aerophagy, whether this is some form of functional dyspepsia or of organic disease, such as gastritis, ulcer, or cholecystitis.

Intestinal Carbohydrate Dyspepsia

The most common cause of intestinal flatulence is carbohydrate dyspepsia (Hurst and Knott, 1931). The envelopes of root vegetables are softened but unbroken by cooking. Under normal conditions amylase of the pancreatic juice penetrates the envelope in the small intestine and converts the starch into soluble sugars, which diffuse into the surrounding media and are absorbed. When owing to abnormally rapid passage through the small intestine some of the starch reaches the caecum the same thing happens there. But whereas in the relatively sterile small intestine very little undergoes fermentation, in the caecum and ascending colon bacteria are so active that fermentation occurs before the sugar has time to be absorbed. Gases and organic acids are produced, the former causing colonic distension and discomfort, and the latter, if in great excess, irritating the mucous membrane sufficiently to cause diarrhoea. The stools are acid, contain many starch granules, and produce much gas on incubation. During the day the gas collects in the splenic flexure and causes discomfort, which is often mistaken by the patient for gastric flatulence and so gives rise to aerophagy. During the night, when the splenic flexure is no higher than the pelvic colon and rectum, the gas moves onwards, and the discomfort in the lower abdomen is often enough to interfere with sleep until relief is obtained by the passage of odourless flatus. Intestinal carbohydrate dyspepsia can be controlled by giving a diet containing no root vegetables or rice; in severe cases the use of other starchy foods must also be limited. As there is no deficiency of amylase the administration of vegetable diastase is useless. The number of enterococci in the stools is increased owing to the excess of carbohydrate in the colon acting as an excellent culture medium; the intestinal flora return to normal when the condition is relieved by dieting. It is obvious that nothing could be more futile than treating cases of this kind by vaccination with the patient's enterococci or by intestinal lavage, though many patients receive such treatment owing to failure to look for starch in the stools and to see whether fermentation occurs on incubation.

Eventration of the Diaphragm

In certain conditions gas accumulates in the stomach or the colon immediately beneath the diaphragm under excessive tension, with the result that the left dome is displaced upwards into the thorax, so that it is higher than the right dome and may even give rise to dextrocardia. Eventration of the diaphragm produced in this way is very much commoner than that resulting from congenital atrophy of its musculature, for which the name has generally been reserved.

(a) AÉROGASTRIE BLOQUÉE

The gas bubble seen with the x rays under the diaphragm is derived from air swallowed with each mouthful of food and drink. It is permanently absent only in achalasia of the cardia, in which the contents of the dilated oesophagus act as a lock, preventing the passage of swallowed air (Fig. 2). Excess is normally removed

FIG. 2.—Achalasia of the cardia, showing absence of gastric air bubble owing to lock formed by food and saliva permanently filling the lower six inches of the dilated oesophagus.

by unconscious silent eructation in the day and through the pylorus at night, when the horizontal posture makes this possible. In rare cases eructation is prevented by spasm of the lower end of the oesophagus just above the sphincter owing to the presence of a simple oesophageal ulcer (Hurst, 1934a). Enormous quantities of gas collect in the stomach and may cause intense pain, increased each time any food or saliva is swallowed owing to its admixture with air. Failure to recognize the true nature of the condition may have a deplorable effect upon the patient's nervous system. This was the case in a man of 76, who had suffered from "gas pains" since 1926. In 1929 and again in December, 1931, he had a small haematemesis; on both occasions he was x-rayed, but nothing beyond excess of gas in his stomach was discovered. Early in 1932 he noticed that when he swallowed there appeared to be an obstruction at the entrance into his stomach, as the passage seemed to "shut up" in a painful spasm whenever food reached it, this being followed by regurgitation of the food with excess of mucus. An x-ray examination again showed no abnormality, except an enormous gas bubble in the stomach, which caused the left half of the diaphragm to be elevated above the right (Fig. 3). He was regarded as hysterical and was treated by various forms of psychotherapy on the Continent, in America, and in England, but without success. His condition became progressively worse, and when I first saw him in January, 1932, he was intensely depressed and was terrified at the mere idea of eating. When a meal was brought into the room his face became anxious and his hands shook. Several minutes elapsed before he could persuade himself to lift the fork in his trembling hands to his lips, and he masticated much more than was necessary in order to put off the moment of swallowing as long as possible. He had lost much weight and strength. As it seemed impossible that such severe dysphagia could be purely nervous in origin, especially in view of the history of haematemesis, a further radiological examination was made, and Dr. P. J. Briggs succeeded in demonstrating the presence of a deep chronic ulcer just above the cardiac sphincter (Fig. 4). The enormous gas bubble in the stomach was clearly a result of the oesophageal spasm caused by the ulcer interfering with the escape of swallowed air upwards, just as it interfered with the passage of food downwards. He was treated with a diet of citrated milk and with atropine, and rapidly lost his pain and dysphagia; he became comparatively happy, but the physical signs of fear were

lesions of the prestate, and the conflicting results reported in cases of breast lesions, tend to detract somewhat from its value. Under these circumstances further investigations of the urinary prolan A content should, in our opinion, continue to be made on lesions of all types involving either the primary or the secondary sex organs, with a view to clarifying the position. The following investigation is therefore offered as a contribution towards this end. During the period covered by this investigation sixty-six cases from the surgical and gynaecological wards were examined. These, as might be expected, consisted mainly of lesions of the secondary sex organs, though they included a few of the ovary and the testis as well. The cases were distributed thus:

Breast (including carcinoma, sarcoma, duct papilloma, chronic mastitis, cysts, acute and chronic abscesses)	28 cases
Prostate (all benign adenomatous enlargement)	32 "
Testis (teratoma)	2 "
Ovarian cyst	1 case
Uterine fibroid	1 "
Chorionic epithelioma (see discussion)	1 "
Pituitary (eosinophil adenoma)	1 "

The method used to determine the amount of prolan A in the urine was that described by Ferguson (1933). The early morning specimen of urine was acidified when necessary and was concentrated by the alcohol-ether method. This concentrated extract was injected into virgin female albino mice not more than 3 weeks old. Three mice were used for each specimen, and received doses of 0.1 c.cm., 0.2 c.cm., and 0.4 c.cm. of the extract respectively. Five injections in all were given to each mouse, two on the morning and evening of the first day, two at the same times on the second day, and one on the morning of the third day. The mice were killed 100 hours after the first injection and their ovaries removed and examined macroscopically at once, and later microscopically. The reaction obtained was judged according to Ferguson's notation (1933):

Reaction I: Hyperaemia and swelling of Graafian follicles with formation of cumulus oophorus.

Reaction II: Massive haemorrhage in ripened follicles.

Reaction III: Corpus luteum formation.

The presence of one or more of these reactions in the sections of the mouse ovaries was considered to denote

Urinary Prolan A Secretion in 66 Consecutive Cases of Lesions of Primary and Secondary Sex Organs

Group	Organ	Lesion	Before Operation		After Operation

a positive reaction. In all sixty-six cases the urine was investigated before operation, and in twenty-five of them the test was repeated ten to fourteen days after operation to see if any change had occurred. The results obtained are tabulated in detail at the foot of the preceding column.

Discussion of Results

Group A: Breast.—Of the twenty-eight cases of varying breast lesions investigated, two unexpectedly gave positive results—namely, "acute abscess" and "tuberculous mastitis." One of these cases was that of a married woman aged 23 who came to the casualty department with an acute abscess in the left breast which had developed on a painful breast of two months' duration following an attack of influenza. The abscess was drained and recovery was uneventful. Examination of the breast at that time produced no evidence of pregnancy enlargement, nor was there any suggestion from her or from the clinicians that she was pregnant. Some months later, however, when she was personally visited it was discovered that she had been delivered of a child six months after the breast abscess had been drained. She must therefore have been three months pregnant at the time the urine was examined, and this obviously explains the positive results obtained both before and after the treatment. The case of tuberculous mastitis occurred in a married woman aged 33 whose youngest child was nine years old. She had had a miscarriage four months before coming to hospital, but stated that since then she had not missed a period. On admission she complained of a painful lump in the left breast that had been increasing in size for the last three months, and of a discharging sore that had been present for four years. Clinically the lump appeared to be malignant, and radical mastectomy was performed. The pathological report, however, showed tuberculous mastitis, but there was no evidence of carcinoma. The positive reaction was given only by the mouse which had received five doses of 0.4 c.cm. concentrated urine, one ovary showing an area of haemorrhage and a corpus luteum, and the other showing the presence of two corpora lutea. This positive reaction cannot be explained unless at the time the patient was pregnant and the pregnancy had a short duration and was terminated without her having been aware of the fact. It is also just possible, since the reaction was given by only one mouse, that this particular mouse was older than had been specified by the dealer, though in size it was similar to the other two used for the test. Apart from these two suggestions I can offer no explanation of the positive reaction in this case. The results obtained in this group of breast lesions were persistently negative, save for one explicable case and one doubtful result.

Group B: Prostate.—All the cases of benign enlargement of the prostate, both before and after operation, gave negative results, indicating that the hypertrophy of the prostate which develops in later life cannot be correlated with that form of pituitary activity which is associated with an increased excretion of prolan, and also that the Aschheim-Zondek test has no diagnostic value in this condition.

Groups C and D: Mixed.—The only case of pituitary adenoma (associated with acromegaly), occurring in a woman aged 32, gave a negative result, which is consistent with the findings of Watts (1932). The two cases of teratoma testis were both positive, and fall into line with the findings of other observers (for example, Ferguson, 1933). The other positive case in this group was that of a woman aged 25 who complained of a blood-stained

by congenital atrophy of the diaphragm and four cases of *aérogastrie bloquée*. It is remarkable how trivial the symptoms of megacolon may be, the condition often being recognized by the discovery of an enormous gas-containing loop of pelvic colon under the diaphragm in the course of a radiological examination of a patient suffering from nothing more serious than chronic constipation. In a minority of cases recurrent attacks of severe pain from partial volvulus of the dilated pelvic colon occur. Gradual dilatation of the anal sphincter and complete evacuation

FIG. 7.—Woman aged 43. Megacolon showing collection of gas in greatly dilated loop of pelvic colon reaching both domes of the diaphragm.

FIG. 8.—Same case as Fig. 7, after escape of gas under high pressure through tube passed per anum, showing descent of diaphragm from the level of the ninth to that of the eleventh vertebra.

of the colon generally result in complete and permanent relief, although the pelvic colon remains abnormally distensible. In exceptional cases a partial twist of the uppermost part of the pelvic colon prevents the escape of the accumulated gas and painful attacks of partial volvulus may continue. It is sometimes possible to evacuate the air-lock by means of a tube (Figs. 7 and 8). In other cases it may be necessary to excise the volvulus during a quiescent period. I have never found it necessary to advise sympathectomy.

OUTPUT OF PROLAN A IN URINE IN CERTAIN EXTRAGENITAL CONDITIONS

REPORT OF AN INVESTIGATION

BY

DOROTHY WOODMAN, M.D., M.Sc.

(From the Department of Pathology, University of Bristol)

It is now a well-established fact that in certain tumour conditions of the male and female genital organs the excretion of prolan A in urine is in excess. In the literature the reports in connexion with the relation of prolan excretion to hydatidiform mole and chorionic epithelioma of the uterus on the one hand, and to teratoma and chorionic epithelioma of the testis on the other, are so extensive, and have been so well summarized by Hamburger (1933), that only a few references which bear directly on this investigation will be mentioned. Since Hamburger's publication many workers have found increased prolan A output in the above conditions—for example, Ferguson (1933), Cutler and Owen (1935), and others.

Earlier Investigations

Ferguson carried out numerous quantitative investigations on urinary prolan A excretion in cases of teratomatous testicular tumours, and it is his technique which has been employed in this investigation. He found that 50 to 50,000 mouse units of prolan A per litre of urine were excreted, the amount varying with the embryonal character of the tumour, the extent of the disease, and the status as regards treatment. His work appears to show that the prolan A estimation has a definite clinical value in the diagnosis and prognosis of these cases.

The work recorded in connexion with secondary sex organs and pituitary adenomas is not so extensive as that which has been carried out on the primary sex organs, and the results are not conclusive. In connexion with breast tumours, Engel (1930) and Saphir (1934) investigated a few cases of breast cancer and obtained no positive results. Zondek (1932) and Baudler (1935), however, obtained varying results in patients with similar lesions, some giving a positive and others a negative prolan A reaction. More recently Taylor (1936), dealing with fourteen cases of non-malignant lesions of the breast, found that in three cases of nipple secretion there was a slight increase in the amount of prolan A excreted in the urine. With regard to pituitary tumours Love (1932) reports a case of an adenoma of the pituitary gland in a male which gave a positive Aschheim-Zondek reaction three times as strong as that normally expected in the urine of a pregnant woman. On the other hand, Watts (1932) found no gonadotropic hormone in blood or urine in fourteen cases of pituitary chromophobe and eosinophil adenomas.

I have been unable to discover any record of work on the urinary prolan A content in cases of ordinary prostatic enlargement. The investigations of Burrows (1935), however, appear to have an indirect relation to this subject. He has shown that the effect on the prostate of the mouse of treatment with oestrogenic compounds, which normally are liberated as the result of the action of prolan A, is to produce histological changes resembling in many ways those of benign enlargement in man.

The Present Investigation

The Aschheim-Zondek test is of such generally recognized value in pregnancy and in the somewhat restricted conditions of chorionic epithelioma and teratoma that the paucity of information in this connexion is

Apart from inherent sensitiveness, the fact that the membranous labyrinth is enclosed in a bony cavity filled with liquid renders it extremely appreciative of changes in tension. Trivial alterations in the air pressure in the middle ear, such as are induced by an obstructed Eustachian tube, may, by the tension transmitted through the oval or round window to the labyrinth, sometimes induce both tinnitus and giddiness.

As part of its inherent sensitiveness the membranous labyrinth is also affected by toxic substances in the blood stream. This explains the feeling of fullness and buzzing in the ears that is induced by certain drugs, such as quinine and salicylates, and by other substances, such as tobacco. Being situated in the base of the skull the labyrinth is also apt to suffer injury either from concussion or from an actual fracture of the bony capsule within which it is contained. Finally, being situated in close relation to the middle ear, it suffers occasionally by the direct spread of infection from the middle ear.

Types of Giddiness

From the point of view of diagnosis it is important to recognize the following types of giddiness which may be met with as a result of labyrinthine derangement:

1. Typical semicircular canal attacks in which the patient has the feeling that objects are rotating around him or that he is himself rotating.
2. A sensation of being forced to one side or the other, which sensation may be actually accompanied by an inability to walk straight.
3. Attacks in which the patient is suddenly thrown to the ground, either forwards or backwards, as if he had been hit on the head by a hammer. This is possibly due to involvement of the otolith organs.
4. The occurrence of a more or less constant unsteadiness, so that the individual has to hold on from pillar to post and both feels and is unsteady.

In almost all cases labyrinthine vertigo may be recognized by the coincidence of auditory symptoms, although in a few instances these may be absent in the early stages. These auditory symptoms consist of tinnitus and deafness. In addition, particularly early in the case, there may be distortion in the hearing of sounds. This distortion may be such that certain tones are heard at a higher or a lower pitch in the affected than in the normal ear. Not infrequently, also, although deafness is present there may be an undue sensitiveness to sounds, so that the hearing of certain tones may be described by the patient as being actually painful.

In considering the clinical picture of giddiness resulting from a disturbance of the internal ear it will, I think, be helpful briefly to mention those conditions the nature of which is firmly established.

Infection of the Labyrinth from the Middle Ear

This may occur as a result of either acute or chronic middle-ear suppuration, and may present itself either as a very acute condition in which the suppuration invades and destroys the whole of the labyrinthine structures, or as one in which there is a more or less localized spread of infection to a portion of the internal ear only. In the former case the patient becomes acutely giddy, with vomiting, violent nystagmus, and incoordination. This giddiness is accompanied by absolute deafness and intense tinnitus on the affected side. Should further complications, such as meningitis, not supervene the acute symptoms gradually subside, and, as has already been said, after a period of a few weeks or months the indi-

vidual learns to be co-ordinate with one labyrinth only. In the latter variety, in which there is a limited and circumscribed infection of the labyrinth, some degree of subjective and objective giddiness is present, and this may occur in attacks with in addition the well-known *fistula sign*—that is, vertigo on increasing the air pressure in the meatus. Certain other diseases may affect the labyrinth. They are:

Mumps.—A rapid effusion into the labyrinth occasionally occurs in this disease, and is characterized by an acute attack of giddiness with absolute deafness during the first week of the complaint, leaving when the acute stage has subsided an absolutely deaf ear. Fortunately the condition is usually unilateral.

Herpes.—This occasionally involves the ganglia of the eighth nerve, not infrequently with an involvement of other cranial nerves, particularly the seventh. This condition produces the typical eruption on the pinna, meatus, and membrane, with acute vertigo, vomiting, nystagmus, and loss of hearing in the affected ear. Unless its existence is recognized the condition is apt to be mistaken for an acute suppuration of the middle ear with a labyrinthine involvement.

Congenital Syphilis.—In about half the cases of congenital syphilis a labyrinthine invasion takes place, accompanied by acute vertigo with vomiting. This as a rule leaves a completely deaf ear, usually on both sides.

Acquired Syphilis.—This does not very often involve the labyrinth, but when it does the picture is a dramatic one. Such involvement occurs as a late secondary manifestation, is bilateral, and gives the picture of an acute destruction of the labyrinth with vertigo, vomiting, nystagmus, etc., the whole process being one of considerable rapidity, with complete destruction of the labyrinth in the course of two or three weeks.

Focal Labyrinthitis

Having briefly mentioned what may be regarded as clear-cut cases of giddiness associated with known diseases of the labyrinth, we are left with a large number of cases in which we have the picture of labyrinthine giddiness but without any of the causes I have detailed. This group of cases has been very ill defined, and as a result of this lack of definition has been given a number of names, such as "Ménière's disease," "aural vertigo," and "neuritis of the eighth nerve." During a period of some years I have been attempting, by an examination of case-records and the obtaining of after-histories, to classify such cases, and have formed the opinion that we are dealing with a distinct and defined disease.

This condition, which I venture to christen "focal labyrinthitis," presents the following picture: It affects both sexes equally, the average age in the series being 47. In more than half the cases the first symptom noted was auditory—for example, deafness and tinnitus—and not vertiginous, and in this former group a period of months or years elapsed before the giddiness began. A defect in hearing in the affected ear is almost always found, and may be extreme in degree up to total deafness. In a few cases, at the beginning of the complaint, a defect in hearing may be absent, but in these the history of a temporary defect during the attacks of giddiness is generally obtained. The deafness is usually variable in degree, as is also the tinnitus. It has been thought that when the hearing in the affected ear was destroyed the giddiness would cease, but my experience shows that this is correct in only half the cases. In addition to the giddiness, during the attacks there is a wide-

discharge for three months following a miscarriage. On examination the uterus was found to be soft and uniformly enlarged to one and a half inches below the umbilicus. No foetal parts were felt per vaginam. The breasts were active, and the diagnosis of a normal pregnancy was made and she was discharged. Two months later she returned, having had a "flooding" ten days previously, when she passed clots and some "white tufts." At this time the uterus was not palpable per abdomen, but was found to be enlarged per vaginam (two to three months). The breasts were still active. A positive Aschheim-Zondek reaction was obtained. As the discharge continued over a period of three weeks it was decided to perform a curettage. The curettings, however, showed only blood clot and fragments of normal-looking endometrium. There were no chorionic villi or other products of conception, and no evidence of hydatidiform mole or chorionic epithelioma. All these observations have been confirmed by subsequent examination of the curettings. Three weeks later the Aschheim-Zondek test was negative. Quite recently, eleven months after the curettage, this patient returned to hospital with a large mass in the uterus which had extended into the vagina. Clinically the mass was diagnosed as a chorionic epithelioma, and a positive Aschheim-Zondek reaction was obtained. She was treated with radium, and a week later the test was repeated and was found to be still strongly positive. She died a day after the last test, and at the post-mortem examination a large mass of growth was found in the uterus and vagina, with metastatic nodules in the lungs. Microscopically the tumour was a typical chorionic epithelioma. The case is included in this series because of the interesting sequence of events. It is obvious that in the beginning a normal pregnancy was present; hence the positive reaction. The pregnancy terminated in an abortion, which explains the curettage findings and the negative test. Some residual chorionic tissue must have been present, since a chorionic epithelioma later developed, but at that stage it was not sufficient to give a positive Aschheim-Zondek reaction.

Summary

The results of Aschheim-Zondek tests on urines from patients with diseases of the secondary sex organs show that, with one possible exception, lesions of the breast and prostate are not associated with any increase in prolan A excretion in the urine. Among additional cases examined the positive results obtained with chorionic epithelioma, teratoma testis (two cases), and an unsuspected case of pregnancy confirm previous findings in these conditions, and the negative results in cases of ovarian cyst, uterine fibroids, and pituitary eosinophil adenoma are in keeping with the majority of previous observations.

I should like to record my thanks to Dr. Fraser and Dr. Taylor and the clinical staffs of the Bristol Royal Infirmary and the Bristol General Hospital for collecting the material for this investigation. The expenses of the work were defrayed by a grant from the Colston Research Committee.

LABYRINTHINE GIDDINESS ITS NATURE AND TREATMENT

BY

A. J. WRIGHT, M.B., F.R.C.S.

Surgeon to the Ear, Nose, and Throat Department,
Bristol General Hospital

Giddiness is a vague term, and includes a very large number of conditions in which the patient either feels unsteady or is unsteady on movement. I propose to confine myself to cases in which such unsteadiness is due to a derangement of the internal ear or labyrinth, partly because this is a very common type and partly because it is the only one about which I can speak with any degree of confidence.

Some Anatomical and Physiological Points

The first problem presenting itself is to decide whether the giddiness is labyrinthine or not, and it might help if I first briefly run over some anatomical and physiological points in relation to the internal ear, as helping to clarify the picture. The internal ear consists of a very delicate perceptive nerve apparatus enclosed in a series of intercommunicating fine membranous tubes and small chambers filled with fluid (the endolymph), surrounded by fluid (the perilymph), and suspended in a dense bony capsule. The anterior portion of the membranous labyrinth we know as the cochlea, and its function is confined to hearing. It is, I think, now established that the perception of different tones is a function of the cochlea, and the analogy of a piano or other stringed instrument, each string being associated with a different tone, is near enough to the truth for our purpose. The posterior portion of the membranous labyrinth consists of the semicircular canals and otolith organs, which together constitute the vestibular apparatus. The function of this apparatus is to assist in the co-ordination of movement by informing the centres of the position or movement of the head in space. While the semicircular canals take note of turning movements, the otolith organs probably appreciate movements in a horizontal or vertical plane.

From a physiological point of view both the auditory and the vestibular organs are extremely sensitive, but while the stimulation of the auditory organ is recognized by our consciousness, normal stimulation of the vestibular organ is not. Our own experience, however, in crossing the Channel, ascending in an aeroplane, or, if we belong to the Victorian era, waltzing in the old style, teaches us that a relatively moderate degree of excess of normal stimulation will both impress our consciousness and produce a widespread disturbance of the vegetative nervous system as shown by nausea, vomiting, pallor, sweating, etc. Fortunately, however, this organ, although extremely sensitive, is adaptable, with the result that Nelson was able to win battles at sea and Miss Colledge is able to spin on skates at an incredible speed and stop instantaneously without feeling any discomfort.

While from the examples I have given we appreciate that giddiness results from overstimulation of the vestibular apparatus, it may also occur as a result of the unbalanced action of the two sides. Thus if the labyrinth be destroyed on one side, for a time the individual is inco-ordinated and therefore giddy; but experience shows that in the course of a few weeks or months this also is allowed for, and both the unsteadiness in movement and the subjective giddiness pass off, the individual becoming normal, at any rate for the ordinary movements of everyday life.

INTERNAL STRANGULATION THROUGH AN APERTURE IN THE MESENTERY

BY

JOHN A. BATY, F.R.C.S.Ed.

Honorary Surgeon, Rotherham General Hospital

Of the uncommon varieties of internal strangulation of the bowel probably that associated with a hiatus in the mesentery is the most seldom encountered, and in consequence few cases have been recorded. A married woman aged 33 who presented this unusual condition was admitted to the Rotherham General Hospital twenty hours after the onset of her symptoms.

Case Record

About 7 p.m. on the day before admission the patient was suddenly seized with severe abdominal pain which doubled her up. Nausea was present, but no vomiting occurred until after castor oil had been given a few hours later. The purgative aggravated her pains, and vomiting became frequent and distressing. Her symptoms were attributed to tinned fish which she had eaten a few hours before the onset of the pain, and food poisoning had been suggested. Colicky pains continued throughout the night and vomiting of brownish fluid persisted; the patient would experience an acute pain that doubled her up, this being followed by an abdominal rumble, with temporary relief. A movement of the bowels took place in the morning, faeces but no flatus being passed. By this time there had been a marked deterioration in the woman's general condition, and when again seen by her doctor an intra-abdominal catastrophe was suspected. She was sent into hospital with a diagnosis of internal haemorrhage on account of her marked pallor and rapid pulse.

Past History.—No dyspepsia had been experienced. On direct questioning the patient recalled vague abdominal discomfort during the past few months. The bowels had always been regular. Periods were normal, the last one having terminated a fortnight before admission. In addition to having three children she had had a four-months miscarriage in January, 1937.

Examination.—When examined the patient was in a collapsed state, with a definite cyanotic tinge showing through her pallor. The temperature was subnormal, the respirations 25 per minute, and the pulse 130. Systolic blood pressure was in the region of 90 mm. Hg. The abdomen was slightly distended and showed limited movements with respiration. Generalized abdominal tenderness was present, but the maximum tenderness was immediately above the umbilicus and towards the right iliac fossa, in both these areas some muscle-guarding being detected. Dullness was noted in the flanks. No tenderness was elicited in the pouch of Douglas and no intra-abdominal swelling could be palpated. The hernial orifices showed no abnormality. Examination of the urine revealed no sugar and no albumin. Taking into consideration (a) the symptoms and signs of acute intestinal obstruction, (b) the severe shock, (c) the absence of external herniae, a provisional diagnosis of acute internal strangulation was made, acute pancreatitis being considered as a secondary possibility.

Pre-operative Treatment.—For three-quarters of an hour before operation the patient was kept under a shock cage; during this time two pints of normal saline were given subcutaneously. One-quarter grain of morphine and 1/100 grain of scopalamine were administered hypodermically half an hour before leaving the ward.

Operation.—At 2 p.m., under local anaesthesia (novocain), the abdomen was opened through a right paramedian split-rectus incision, which extended an equal distance above and below the umbilical level. A large quantity of clear brownish fluid escaped on opening the peritoneal cavity. No fetor was present. The caecum was collapsed, and to its left side a mass of distended bowel could be palpated. On further investigation it was found that about four feet of the lower ileum

had passed, from below upwards, through a large defect in the terminal part of the mesentery. In addition the herniated ileum had undergone torsion in an anti-clockwise direction. The bowel was purple and tense; it was reduced without great difficulty and soon recovered its normal colour. It was noted that the hiatus in the mesentery lay between the ileo-colic artery and the lowest mesenteric branch. These arteries ran along the free margins of the opening, which extended up to near the site of origin of the ileo-colic artery. No attempt was made to close the gap, as this would have prolonged operation unduly. Accordingly, having relieved the strangulation and made certain the bowel was viable, the abdomen was closed in layers.

Diagram showing the position of the mesenteric hiatus.

Post-operative Treatment.—In addition to maintaining the body temperature a continuous intravenous saline drip was instituted, after having first given intravenously 20 c.c. of 15 per cent. sodium chloride. The patient's general condition improved considerably, the pulse falling and improving in volume. There was no vomiting, and colicky pains no longer caused distress. The improvement was maintained for eight hours after operation, when a sudden collapse took place, the patient dying within a few minutes of the onset of the collapse. No permission for a necropsy was obtained.

Commentary

There are a number of interesting features about this case when it is considered not only from the point of view of the abnormality discovered but also from the clinical and pathological aspects in relation to acute intestinal obstruction. The way in which the ileo-colic and terminal mesenteric vessels lay actually along the free margins of the opening was striking: the appearance did not in any way suggest that trauma at an earlier date had caused a small primary tear in this area. There seems to be little doubt that the mesenteric aperture was congenital in origin.

Clinically, in the absence of external herniae the symptoms and signs of acute intestinal obstruction with superimposed shock suggested internal strangulation. The acute onset with rapid deterioration in the patient's condition, together with consideration of the maximum point of tenderness, made small-bowel strangulation a more likely possibility than a colon volvulus. The profound nature of the shock made one think that there was more than a mere knuckle of bowel strangulated. It is well known that acute pancreatitis may closely simulate acute intestinal obstruction, but when one bore in mind the age, sex, and build of this patient, together with the absence of antecedent dyspepsia and also the position of the maximum tenderness, acute pancreatitis became only a second possibility.

spread upset of the vegetative nervous system, giving rise to nausea, vomiting, sweating, pallor, and not infrequently diarrhoea, the general picture of sea-sickness being closely reproduced. The middle ear is usually normal, the proportion showing some changes in the tympanic membrane being not greater than is met with in a similar group in which vertigo is absent. On careful search a focus or foci of infection can be found in all cases, most usually in maxillary antra, tonsils, or teeth. In regard to the antral cases it is interesting to note that the infected side does not necessarily coincide with that in which the ear is diseased.

The course of the complaint is infinitely variable, long periods of partial or complete freedom from giddiness occurring, perhaps alternating with attacks of extreme severity, and this fact renders it very difficult to assess with certainty the results of treatment. The disease is a progressive one, as evidenced by the defect in hearing, and its duration in the cases under review varies between the limits of two and thirty-nine years. Although there is a temporary ebb and flow in the course of the complaint I have not as yet met with a case in which spontaneous cure has taken place, as judged by the hearing.

I find on examination of my records of cases which I have had under observation from the beginning and subsequently over a long period that in all cases the initial diagnosis was one of middle-ear or Eustachian catarrh. This diagnosis was based, I find, on tradition and on the observation that inflation usually produced some improvement in the hearing. The subsequent course of these cases has convinced me that this initial diagnosis was mistaken and that the condition was a labyrinthine one from the start.

Treatment

Labyrinthine giddiness occurring in cases of middle-ear suppuration is usually an indication for operative drainage of the middle-ear cavities. Formerly, in addition to such drainage of the middle ear and mastoid, an attempt was made by many to pursue the infection into the labyrinth also. This surgical adventure never appealed to me, and I think it is now largely abandoned as being more likely to expedite the spread of infection to the cranial cavity than to prevent it. In the case of giddiness due to labyrinthine involvement in mumps or herpes no treatment is available. In the case of syphilis any evidence of labyrinthine involvement, as shown by giddiness and defect in hearing, is an indication for immediate and thorough treatment of the disease.

In the remaining and far greater number of cases, which I have designated "focal labyrinthitis," careful search for a septic focus or foci, followed by their appropriate treatment, which is usually operative, will, in my experience, give very satisfactory results so far as the giddiness is concerned. My results are as follows:

All cases treated in this way—that is, by the eradication of a septic focus or foci—have been included, and, with two exceptions which are mentioned below, these patients are now completely free from vertigo. The total number is twenty-three, and in ten of these what may be described as a cure resulted—that is, both the cessation of the vertigo and the return of the hearing to normal. In a further three cases the vertigo ceased and some improvement took place in the hearing; in eight the vertigo ceased but the hearing remained unaltered. Of the remaining cases, in one the tonsils were removed a year ago without any diminution in the vertigo, but recent examination has

shown some dead and infected teeth, which may be regarded as responsible. The other failure is represented by a case of twelve years' duration in which intranasal drainage of the maxillary antra has produced no improvement. Recent examination of this case suggests that a chronic tonsillitis may be responsible, and removal of the tonsils has been advised. I feel that, although the number of cases is small, in view of the fact that all are included and that the results are so uniform one must regard them as whole-heartedly supporting my hypothesis.

Finally, as it is sometimes helpful to excise an eye which is hopelessly disorganized by inflammation and which is of no functional use, so is it desirable to destroy a diseased labyrinth that, while no longer useful for hearing, is still producing distressing vertigo. Various methods have been employed to this end. The earliest was the opening of the labyrinth either through the promontory or the external semicircular canal. Later the opening of the external canal was augmented by the injection of alcohol along its lumen into the centre of the labyrinth; and recently cranial surgeons have been increasingly advocating and employing division of the eighth nerve within the skull for the relief of giddiness. Some three years ago the idea occurred to me of injecting alcohol into the labyrinth through the intact membrane and the footplate of the stapes. After a considerable amount of preliminary experimental work I have now carried out this procedure on a number of cases and am satisfied that it achieves the desired end without any appreciable risk to the patient. The procedure necessitates a general anaesthetic, of only very short duration, and the method is therefore particularly applicable to aged or debilitated individuals.

Summary

1. Giddiness due to derangement of the labyrinth is common.
2. Of such cases of giddiness a very considerable proportion are of doubtful nature, and have been given such names as "Ménière's disease," "aural vertigo," etc.
3. As a result of the clinical study of some seventy cases I believe that the labyrinthine derangement is inflammatory and secondary to a focus of infection.
4. The favourable results following the eradication of a focus of infection strongly support this hypothesis.
5. The injection of alcohol through the intact tympanic membrane and footplate of the stapes offers a simple and satisfactory alternative to the surgical opening of the labyrinth or division of the eighth nerve.

The third International Goitre Conference will be held in Washington from September 12 to 14. On the first day attention will be paid to endemic goitre, cretinism, and myxoedema, with special reference to aetiology, pathology, types, geographical distribution, iodine, prophylaxis, thyroiditis, and malignant goitre. On the second day the thyroid will be considered in relation to metabolism, nutrition, and the endocrine glands, comprising a study of its physiological and pathological interrelationship and the clinical application thereof. On the concluding day hyperthyroidism will be discussed, including questions of metabolism, iodine, complications, recurrences, and "goitre heart," with consideration of the diffuse and nodular toxic goitre types and the surgical and medical treatment. The official language of the conference is English; interpreters will be available for papers read in other languages. The papers read and the speeches made will be published afterwards in the form of *Transactions*. Further details may be had from Dr. Allen Graham, 200 East 93 Street, Cleveland, Ohio.

ring to general paralysis of the insane, states: "The intrinsic muscles of the eyes are affected in some stage of the disease in almost all cases. The first eye symptom is usually an inequality of the pupils with a sluggishness on the part of the larger pupil to contract to light, accompanied by an absence of the usual dilatation following cutaneous stimulation, while all other reflexes are perfectly normal." He quotes Bevan Lewis, who described an early inequality not associated with impairment of the pupillary reflexes and probably due to a cortical lesion, and a late inequality associated with absence of reaction to light and other stimulation and probably due to advancing spinal and bulbar disease.

Apart from the cases of general paralysis of the insane referred to above none of our cases showed evidence of mental disorder associated with anisocoria. Ten men stated that their skulls had been fractured, and in two of them bony depressions were felt. It is recognized that the nature and consequences of past head injuries are often difficult to assess from the history given by a law-breaker, but a reliable history of a severe head injury with concussion was obtained in sixteen other cases.

As to local eye conditions, sixty-two men had different errors of refraction in the two eyes with no obvious abnormality. Nine suffered from strabismus, and in ten the inequality was the result of trauma. Seventeen suffered from cataract, corneal ulceration, congenital ptosis, disseminated choroiditis, diabetic retinitis, and other ocular disease.

Anisocoria was associated in one case with aneurysm of the thoracic aorta, and in three cases with aortic lesions. One subject gave a history of tuberculous disease of the right apex, which was quiescent at the time of examination; in two cases parenchymatous goitre was present, and in one torticollis. In 139 cases both history and clinical examination proved negative. It is interesting to note that only seventeen out of the total of 295 men were aware of the pupillary inequality—seven in consequence of their own observations, while the remaining ten had been informed of the fact by their medical attendants.

The question of the relation between the degree of inequality and the pathological condition is of considerable importance. Our figures show that a minor degree of inequality was present in approximately 63 per cent. of our cases of anisocoria, a medium degree in 32 per cent., and a gross inequality in only 5 per cent. Further, it appears that minor degrees of inequality are most common when the anisocoria is a physiological abnormality or is due to a difference in refraction, whereas a gross inequality is more frequently a result of injury or disease. It may be said with some degree of confidence that persistent major degrees of inequality indicate a definite lesion, whether due to disease or injury, and in this respect our findings agree with the statement of French, that "pronounced difference in the size of the pupils may be symptomatic of some organic lesion."

Conclusion

To recapitulate, of 3,000 unconvicted male prisoners 295 showed persistent anisocoria. No pathological condition could be detected to account for the anomaly in 139 (47.1 per cent.); an error of refraction was the only other abnormality in sixty-two (21.0 per cent.); a history of syphilis occurred in thirty (10.1 per cent.); and in the remaining sixty-four (21.1 per cent.) the inequality was due to various causes. Only four were associated with mental disease. The anisocoria was therefore of no significance from the point of view of criminal responsibility in approximately two-thirds of the cases, and in less than half of the remaining third (13.5 per cent.) was associated with syphilis and a history of head injuries, conditions which may be related to mental disorder. It appears, then, that although anisocoria is most commonly a physiological anomaly, it should be regarded with suspicion and of possible

medico-legal significance in medico-legal cases if laboratory tests are not available.

Clinical Memoranda

Multiple Benign Sarcoid and Tuberculous Ulceration

Boeck in 1899 designated as multiple benign sarcoid of the skin the condition which Besnier had described as lupus pernio. The recent literature on this subject was reviewed in the *Journal* of September 11, 1937 (p. 534). The following case in which sarcoid was associated with tuberculous ulceration of the leg seems worthy of being placed on record.

CASE HISTORY

A rubber planter, aged 31, was admitted to the Hospital for Tropical Diseases, London, on April 4, 1934, complaining of ulcers of the left lower leg and a generalized skin eruption of six to seven months' duration. He first went out to the Federated Malay States in 1923, and had resided there ever since, except for two holidays, each of six or seven months, spent in this country. In September, 1933, while on holiday in Scotland, he noticed the left ankle to be a little swollen, and shortly after this a small ulcer appeared on its posterior aspect; this was thought to be due to an insect bite, and consequently was treated with fomentations. The ulcer healed, but the leg felt tired and painful after walking any distance, and three weeks later a rash appeared over the left lower leg posteriorly. In December, while on the way out to the Federated Malay States, this rash spread to the back, to the abdomen, and then over the skin surface of the body generally. On reaching Klang, Federated Malay States, the condition had become that of a healed but bronzed ulcer on the leg, with a number of skin patches resembling the heat spots to which he has always been subject. During January the joints became painful and all cartilages were tender, while the nasal mucous membrane showed slight but definite signs of inflammation; there was no temperature at that time, although shortly afterwards there was slight evening pyrexia, and the old ulcer became inflamed again and the lymphatics in the skin leading from it became raised and hard. Other ulcers appeared over the leg, and the raised, rather lupus-like, but discrete patches on the skin surface generally increased. The Wassermann and Kahn reactions were negative, but blood culture showed a growth of short, delicate, Gram-negative rods; guinea-pig inoculation showed these organisms to be non-pathogenic. Serum precipitation tests for glanders, made both in Kuala Lumpur and in Singapore, were inconclusive. Treatment with lotions and ointments externally, calcium internally, arsenicals intramuscularly, and protein shock was in no way beneficial. The patient then returned to England for further investigation and treatment. During the voyage home two more ulcers appeared on the same leg, and from these a slight serous discharge exuded. The skin eruption was at first itchy, but under the treatment outlined above the irritation subsided. The general health remained good. Apart from malaria in 1927 there was no illness of note, nor was there any familial history of tuberculosis.

DIAGNOSIS AND TREATMENT

On admission the patient was found to be well nourished, with apparently normal mucous membranes and a clean moist tongue. There was no cyanosis of the finger nails and no clubbing of the fingers. The posterior aspect of the left

In previous recorded cases either the contents of the loop had to be aspirated to facilitate reduction or the condition of the loop had necessitated resection, in both instances thus removing the highly toxic contents of a closed loop. In this case such procedures were not needed to relieve the strangulation. Chloride deficiency and dehydration were made good, and before the fatal collapse the satisfactory progress suggested that the post-operative treatment was adequate. Unfortunately this proved to be incorrect. Where large loops have been strangulated, in addition to measures already mentioned a blood transfusion appears desirable in spite of initial satisfactory progress with chlorides and fluids alone. If such a transfusion be given after relief of strangulation it will provide the circulation with healthy blood capable of more effectively neutralizing toxins. It would be helpful to know whether routine aspiration of large strangulated loops to remove toxins which otherwise would be absorbed with the restoration of loop circulation gives the patient a better chance of recovery.

THE INCIDENCE OF UNEQUAL PUPILS IN UNCONVICTED PRISONERS *

BY

HARVIE K. SNELL, M.D., D.P.H.

Medical Officer, H.M. Prison, Liverpool

AND

GEORGE A. CORMACK, M.B., B.Sc.

Medical Officer, H.M. Prison, Brixton

The incidence of inequality of the pupils in pathological states and as a physiological anomaly is generally recognized. Collier and Adie (1926) say: "Inequality of the pupils occurs in connexion with all nuclear and peripheral ocular paralyses, and with cervical sympathetic paralysis. It accompanies all defects of vision from lesions of the visual path between the eye and the external geniculate bodies, provided the appreciation of light be unequal in the two eyes. It may be congenital or associated with inequalities of the refraction of the two eyes, and then has no pathological significance. It is commonly a sign of nervous syphilis." French (1936), writing on the same subject, declares: "Inequality in the size of the pupils is observed frequently and may have no pathological significance. . . . In cases of marked inequality of the pupils one may suspect tabes, general paralysis of the insane, a unilateral lesion of the third nerve or cervical sympathetic, trigeminal neuralgia, carotid or aortic aneurysm, a unilateral intracranial lesion, or glaucoma." Firth (1914) states: "Anisocoria without impairment of the pupillary reactions is not necessarily a serious symptom, for it may occur in healthy persons. Here the difference is usually not more than half a millimetre, and rarely as much as one millimetre; the inequality persists in all states of illumination and convergence. Inequality associated with change of the pupil reactions may be taken as evidence of an organic lesion."

The significance of anisocoria as an indication of mental disorder in medico-legal cases may be uncertain unless the cerebrospinal fluid is examined; but the medical officer is seldom in a position to urge this if the accused is charged

with a minor offence and appears to be mentally normal. It therefore seemed desirable to investigate the matter further, and 3,000 men received into Brixton Prison were examined to ascertain the proportion of cases presenting anisocoria and to determine its relative frequency in the group when associated with declared organic nervous disease or mental disorder. For this purpose comprehensive notes were made on the history of each case, with particular reference to venereal disease, nervous and mental disease, head and eye injuries, and other relevant factors. A physical examination of the various systems followed, with ophthalmoscopic examinations and tests for errors of refraction. The subjects were also examined in regard to their mental conditions. All cases of anisocoria were examined on the evening of their reception and again the following morning. In many cases the inequality noted overnight was no longer present at the second examination. This was found to apply to cases of minor and major degrees of inequality. The total number of cases showing anisocoria on reception was 576. Of these, 281 (48.8 per cent.) were rejected on subsequent examination on account of the transient nature of the inequality. This could not be attributed to any difference in light intensity, and it was thought that fatigue was probably the determining factor. In the evenings the pupillary reaction was less sensitive, the pupils somewhat more dilated, and consequently any inequality more marked.

There can be little doubt that anisocoria, particularly if non-pathological, is subject to considerable variation, and pupils which at one period are definitely unequal may at other times be equal. This applies also, to a lesser extent, in cases of anisocoria associated with disease of the nervous system. In this connexion Firth (1914) states: "Inequality of the pupils occurs in many organic nervous diseases, and also in functional disorders: the condition may be transient, constant, or subject to change. The degree of anisocoria may vary from day to day, even from hour to hour."

Method of Classification

Of the total cases examined 295 (9.8 per cent.) were found to have persistent anisocoria. They have been classified into three groups, according to the degree of inequality and which pupil was the larger:

Left Pupil					Right Pupil				
110 +	75 +			
54 ++	41 ++			
9 +++	6 +++			
173						122			

Conditions Associated with Anisocoria

Thirty of the cases gave a history of syphilis: four of these were diagnosed as suffering from general paralysis of the insane; seven showed other signs of neurosyphilis; and in five the pupillary reactions were abnormal without other clinical evidence of neurosyphilis. There was apparently no clinical relation between the stage of the disease and the degree of inequality. In the remaining fourteen cases there were no clinical signs of syphilitic disease of the nervous system. In one case of neurosyphilis with marked pupillary inequality the condition was congenital. In another case, with a history of syphilis but without signs of any specific lesion, the inequality was due to an accident, in which the patient had been struck a blow on the eye, with subsequent retinal degeneration.

Inequality of the pupil may be present with only a slight modification of the pupillary reflexes in early cases of neurosyphilis. It may be the first ocular sign and one of the earliest indications of the involvement of the nervous system. There can be little doubt that anisocoria associated with changes in the pupillary reaction invariably indicates a definite organic lesion, and is often accompanied by other signs of the disease. Reviews

HEPATITIS

Les Hépatites. By Maurice Loeper. (Pp. 262; 47 figures. Fr. 60.) Paris: Masson et Cie. 1937.

Professor Maurice Loeper, who is well known as a distinguished authority on diseases of the digestive tract, has here brought together a series of studies on inflammation of the liver substance. Hepatitis is now recognized as the essential pathological state in affections of the liver. In so-called catarrhal jaundice it is no longer allowed that an infective process has spread from the intestine to the liver by way of the bile ducts. The catarrhal plug of mucus at the ampulla of Vater observed by Virchow is now regarded as secondary, the primary state being a toxic alteration of the liver cells. Some of the toxins, those which produce the severe or malignant type of yellow atrophy of the liver, acute or subacute, are known, such as arsenic, mercury, gold, atophan; there is the form due to infection with the icterohaemorrhagic spirochaete, with an established clinical form; while the ordinary infecting bacteria of the alimentary tract may be responsible for the milder cases. All forms from the severest to the most benign have demonstrable inflammatory lesions of the liver cells, and clinical tests of liver function—coefficient of urea to residual nitrogen of the blood, galactose retention, bilirubin of the blood—show a deterioration of liver efficiency. Though biliary lithiasis is a humoral complaint, the jaundice associated with gall-stones in the ducts is not always a jaundice of retention; Professor Loeper demonstrates that there is often hepatitis and recommends early surgical intervention for treatment. This lends additional emphasis to the old dictum of Chauffard: If certain of an obstruction one operates, even if doubtful one still operates, and the earlier the better. Operation is often indispensable; it is always justified. Operation is the only means of protecting the liver from serious, often irremediable, damage.

Professor Loeper proceeds to discuss other less well-known aspects of liver disease. The heart is affected in cases of chronic hepatitis, not only by the cirrhotic process tending to dam the blood in the abdominal cavity with consequent insufficient irrigation of the heart and low blood pressure, but by the direct effect of toxins on cardiac muscle or nerves. Cardiac failure in cirrhosis may result mechanically from insufficient perfusion of the liver, or secondarily through alteration of endocrine glands; the suprarenal, thyroid, pancreas, testis, ovary, and hypophysis may all show degenerative changes from toxæmia; and there is the effect of toxins on the myocardium itself. Thus oedema in sufferers from liver disease may be due to fatigue or failure of the cardiovascular system. Other varieties of oedema may be mechanical, or due to concomitant lesions of the endocrine glands or kidneys. Indirectly too there may be an oedema of starvation in severe and cachectic states. The particular form of bronze diabetes leads on to a discussion of melanosis, which is a unity, always, even in bronze diabetes, produced by melanin. The diminution in the oxidation of sulphur appears to be related to lack of ascorbic acid, and both in bronze diabetes and in Addison's disease encouraging results have been obtained by giving ascorbic acid by mouth or intravenously. Professor Loeper adds interesting studies of the telangiectases associated with hepatitis and the tuberculous peritonitis so often found as a complication of chronic liver disease. The book gives a lucid discussion of the problems of liver disease.

FRACTURES, DISLOCATIONS, AND SPRAINS

The Management of Fractures, Dislocations, and Sprains. By John Albert Key, B.S., M.D., and H. Earle Conwell, M.D., F.A.C.S. Second edition. (Pp. 1,246; 1,222 figures. 52s. 6d. net.) London: Henry Kimpton. 1937.

A second edition of *The Management of Fractures, Dislocations, and Sprains*, first published in 1934, brings this valuable work up to date, and it remains a book which the student, the general practitioner, or the surgeon may consult with advantage. It is a practical and comprehensive guide to the treatment of fractures and dislocations, which are considered in detail on a regional plan. Chapters on the Workmen's Compensation Laws and the medico-legal aspects in fracture cases continue to make interesting reading. Chapter XI, on fractures of the skull and brain trauma, was written by the late Dr. Charles E. Dowman not long before he died and has been revised by his associate, Dr. Edgar F. Fincher of Atlanta. The volume is divided into two parts. Part I, which is much the smaller, deals with the principles and general aspects; Part II with diagnosis and treatment of specific injuries. In the latter section a chapter on fractures of the jaws and related bones of the face is written by Dr. James Barrett Brown of St. Louis. The chapter on injuries of the spine is one of the best in the book and has been brought right up to date. Illustrations are abundant but the quality of the reproduction of x-ray films varies somewhat; thus, Figs. 452 A, B are excellent, but Figs. 453 and 454 on the opposite page are poor by comparison. This continues to be an excellent reference work for the practising surgeon.

EYE, EAR, NOSE, AND THROAT

The 1937 Year Book of the Eye, Ear, Nose, and Throat. The Eye: E. V. L. Brown, M.D., and Louis Bothman, M.D. The Ear, Nose, and Throat: G. E. Shambaugh, M.D., E. W. Hagen, M.D., and G. E. Shambaugh, jun., M.D. (Pp. 640; 113 figures; coloured frontispiece. 2.50 dollars or 10s. 6d., postage 6d.) Chicago: The Year Book Publishers, Inc. London: H. K. Lewis and Co., Ltd. 1937.

The issue for 1937 of the *Year Book of the Eye, Ear, Nose, and Throat* fully maintains the standard of previous years. The same arrangement and subdivision of the subject-matter is preserved. In the first part, dealing with the eye, by Professors E. V. L. Brown and Louis Bothman, a few abstracts of particulars may be mentioned. Reitsch reports eczema on his own fingers and even face from the use of pantocain in his practice. Laurell and Heinonen produce experimental and statistical data respectively to show that pediculosis as an important factor in the aetiology of phlyctenulosis and tuberculosis is overrated. Heinsius reports an experimental investigation into the influence of vitamin A on regeneration of the corneal epithelium; and Kugelberg draws attention to the frequent association in Sweden of spasmophilia and cataract. Goerlitz reports the cure of a detachment of the retina in a pregnant woman. The indications for termination of pregnancy in this condition require to be revised since the introduction of the Gonin operation. MacDonald records a case of choroidal chorion epithelioma in a young man. A full description, with illustrations, is given of a method of dacryocystorhinostomy by Wright. Serr reports clinical observations with the new Zeiss projectometer of Maggiore, and points out its advantages over the projection perimeter and Bjerrum screen. Henry Cohen describes two cases of pernicious anaemia in which failing vision with optic atrophy was the first indication.

The section on the ear, by Professors Shambaugh and Hagen, includes several papers on otosclerosis—some on

lower leg showed three small ulcers in various stages of healing, which exuded a slight serous discharge; the surrounding skin presented a bluish-red or violet discoloration and induration. On the skin surface of the body generally, including the face and arms, were numerous pigmented, slightly raised plaques, varying in size from a pin-head to little less than a two-shilling piece, and in colour from rose to light brown; the colour did not alter with pressure. The plaques on the face were not so deeply coloured as those on the body, and while they were present on both surfaces of the arms they predominated on the extensor aspects. There was slight blood-stained crusting of the right nostril. Examination of the respiratory, cardiovascular, gastro-intestinal, genito-urinary, and nervous systems revealed nothing abnormal. There was no elevation of temperature or pulse rate while the patient was in hospital.

X-ray examination of the abdomen revealed a group of calcareous glands in the lower part of the right loin space. The Wassermann and Kahn reactions were still negative. There were 8,000 leucocytes per c.mm., with 49 per cent. neutrophils, 30 per cent. lymphocytes, 7 per cent. large mononuclears, 6 per cent. eosinophils, and 2 per cent. basophils. The faeces showed the presence of ankylostoma ova. A swab from the nose disclosed a few pus cells and Gram-positive cocci. No tubercle bacilli and no *B. leprae* were found. One of the plaques was removed from the back; cultures on different media were negative, but:

"Microscopical examination showed an architecture which was typical of the multiple benign sarcoid of Boeck. There was no definite alteration in the epidermis, but in the corium extending down to near the subcutaneous tissue were deposits of cells situated chiefly about the hair follicles. These cells were of connective-tissue origin, and were round or irregular in shape, with here and there giant cells present. Where the infiltration was densest the connective-tissue stroma was rarefied. The histology differed from that of tuberculosis cutis in the infiltration being more circumscribed, in the almost complete absence of plasma cells, and in the irregular shape of the connective-tissue cells."

A scraping from the edge of one of the small ulcers on the posterior aspect of the left leg, however, showed the presence of tubercle bacilli:

"The ulceration was rather more superficial in type than that which occurs in Bazin's disease (erythema induratum), and suggested that the infective virus was spreading by the lymphatics rather than by being more deeply seated in the veins. At first sight the ulceration recalled that met with in sporotrichosis of the skin, and it was not until tubercle bacilli were found in the scrapings from one of the ulcers that the true nature of the lesions was determined."

The condition was finally diagnosed as that of multiple benign sarcoid of Boeck associated with tuberculous ulceration of the leg. The ankylostomiasis was treated by means of oil of chenopodium, carbon tetrachloride, and magnesium sulphate. The patient was made to rest in bed, while dry dressings were applied to the leg. Potassium iodide was at first administered internally; later colossal bismuth and colossal bismuth ointment were applied locally, and intramuscular injections of bismostab were given; and, finally, injections of sodium morrhuate were given twice weekly. None of these therapeutic measures had any appreciable effect upon the skin condition, but the leg showed some improvement.

The interesting features of the present case were: (1) the association of tuberculous ulceration of the leg with Boeck's sarcoid; (2) the actual finding of tubercle bacilli in the ulcers; (3) the absence of evidence of visceral tuberculosis other than that of a small group of calcareous abdominal glands.

The above case was admitted under Dr. N. Hamilton Fairley, and later transferred to the care of Dr. J. M. H. MacLeod, to both of whom I am indebted for permission to publish the case, and to the latter for his kindness in furnishing me with the detailed histology of the condition.

R. HOWITT WISEMAN,
Medical Officer of Health, Mombasa.

Systemic Embolism as a Complication of Lobar Pneumonia

The following case is of interest on account of the rarity of this complication of pneumonia.

CASE RECORD

A man aged 55, a labourer, was admitted to hospital complaining of pain, swelling, and loss of power in the left forearm, wrist, and hand of six days' duration. For two weeks before the onset of pain his doctor had been treating him for lobar pneumonia, from which he was making an excellent recovery, when one afternoon he developed sudden severe pain in his left arm after a bout of coughing. The arm below the seat of the pain became blanched and later red and swollen. He sent for his doctor, who treated the arm with rest and local application of ichthyol; there was, however, no improvement in his condition after six days, so he was admitted to hospital.

The patient, of an obese plethoric type, still complained of some cough, especially in the mornings. His arm was painful and quite useless below the elbow. On examination the arm was found to be dark blue in colour distal to a line about two inches below the elbow-joint. Above this was an indurated area which gradually merged into normal tissue. The nail beds were quite black, with no circulation evident and no pulse palpable in radial artery. There was slight oedema of the back of the hand. He could bend his wrist through a few degrees, but could not move his fingers. The hand showed typical "claw" deformity, the interphalangeal joints all being flexed, and it was impossible to straighten these by force. There was complete sensory loss in the area.

Examination of his chest revealed some impaired resonance of the right base with coarse crepitations on deep inspiration. His sputum was mucopurulent. No cardiac lesion could be detected on physical examination, and there was no history of cardiac symptoms. The blood pressure was 140 mm. systolic and 90 mm. diastolic. Apart from those changes due to the local condition, no lesion was found in his nervous system. He had no enlargement of liver or spleen; his bowels were regular and his appetite had returned to normal. There was nothing abnormal in his urine. The temperature was 99° F. and the pulse 90.

In view of the history and physical signs a diagnosis of embolism of the brachial artery was made. The arm was wrapped in cotton-wool and kept in a position a few degrees short of extension. Immediate operation was not indicated on account of the duration of the affection. His chest condition improved under treatment with expectorants and tonics; the arm remained in a stationary state for two weeks, dry gangrene of the palm then setting in. During all this time no further localization of the affected area had taken place.

Amputation under local anaesthesia was not favoured by the patient, so three weeks after admission, when his chest had completely recovered, the arm was amputated at the junction of the middle and lower thirds of the humerus under general anaesthesia. He made an excellent recovery, his chest never showing any sign of relapse, the only event being a small boil which developed on the other wrist. This cleared up in a few days with elastoplast, and he was discharged from hospital on November 6, 1937.

DISCUSSION

In view of the history of sudden onset of pain in the arm after a severe fit of coughing, the whole following an undoubted lobar pneumonia, it seems rational to suppose that the pneumonic condition had caused a phlebitis of some of the pulmonary veins with thrombus formation. The undue mobility of the newly expanding lung caused by the strain of excessive coughing had loosened a thrombus which, passing through the left auricle and ventricle, lodged in the brachial artery of the left arm.

Reading.

WILLIAM H. HOOD, M.B., B.Ch.,
Assistant Medical Officer, Battle Hospital.

expounded are now recognized as the serious and pertinent difficulties which they certainly are in the lives of every one of us. The mother and her child, sexual education, nudity, the physical aspects of love, chastity, sexual abstinence, prostitution, venereal disease, marriage with its pleasure principle and its procreative principle—these are the subject-matter of this book, subject-matter which anyone with any interest in the social betterment of the individual or the race must take into account. But it is a book for the intelligent reader: there are no cheap dogmatisms, no facile solutions of these, perhaps at present, insoluble problems.

The author with great erudition relates the experiences and opinions of eminent authorities all down the ages, and his own opinion (if expressed at all, and sometimes we could wish that the opinion of so great an authority as Havelock Ellis were expressed more definitely) certainly does not obtrude. Still, a great deal of information is given, and perhaps it is necessary that everyone should decide for himself, given the premises and arguments, what is the right course to take. As an example of the author's fairness we may refer the reader to the chapters on chastity and sexual abstinence. As he says, continence is always desirable, but it is well to realize that absolute abstinence from any form of sexual gratification whether in fact or fantasy would mean complete sexual anaesthesia, which if it ever existed would be most certainly pathological; hence we cannot generalize as to the how and when and where of abstinence: it must be a separate problem for each individual.

No thinking person ought to burke the problems of sex in society; and he will find the information which he requires, if he is to consider them honestly, set out in this book as completely, as scientifically, and as impartially as he could wish.

Notes on Books

The official *Medical Register* for 1938 has now been published on behalf of the General Medical Council by Constable and Co., Ltd., at 21s., post free 22s. 6d. The table printed in the introductory section shows that 2,214 names were added last year, the highest increment in any year since 1925. New registrations numbered 1,096 in England, 593 in Scotland, 239 in Ireland, and 286 on the Colonial and Foreign lists. The total number of names on the *Register* at the end of the year was 60,163, representing an increase of 1,153. The number of names removed from the *Register* during 1937 was 1,090: of these 957 were deleted on evidence of death; 123 for failure to comply with the inquiries of the registrar as to cessation of practice or change of address; and five were struck off under the disciplinary powers conferred by Parliament on the General Medical Council. The average annual number of penal erasures during the past twenty years was five.

A Concise Pharmacology has been written in collaboration by Mr. F. G. HOBART, the head of the pharmaceutical department of Westminster Hospital, and Dr. G. MELTON, sometime medical registrar of that hospital. The volume is intended for the use of medical students, and the authors have condensed the subject into a pocket volume of 171 pages. The condensation effected is best indicated by the fact that the actions of digitalis are described in less than a page, whilst the actions of potassium iodide and potassium bromide only occupy about a dozen lines each. On the other hand, a number of drugs are mentioned, such as adnota, damiana, lithium salts, oleum rusci, sabal, etc., which are of very secondary importance. The section on the sex hormones fails to

indicate the state of current knowledge on this subject, since it does not distinguish between the scientific status of unstandardized ovarian, orchitic, or prostate substances given by mouth and the preparations of the purified sex hormones. A somewhat unusual feature of the volume is the insertion at its end of a few pages of advertisements, mostly of proprietary medicines. It is published by Leonard Hill, Ltd.

Übungstherapie bei Rheumatischen Erkrankungen. Der Rheumatismus, Volume I, by Dr. P. KÖHLER (Dresden and Leipzig, Theodor Steinkopff, RM.5) is the first contribution to a symposium on rheumatism edited by Professor Rudolf Jürgens. Dr. Köhler here describes the treatment of chronic rheumatic conditions by small movements carried out by the patients against the resistance of graduated weights attached to the limb over pulleys. These are adapted to both large and small joints. The simplicity of the apparatus is shown in illustrations.

Preparations and Appliances

SIMPLE EXTENSION APPARATUS

Mr. M. D. SHEPPARD (Chelmsford, Essex) writes:

The illustration below depicts an apparatus for attachment to the end of a standard hospital bed. It serves for the support of a Thomas's splint, and also has fixed to it a pulley to allow extension of the limb, either through a Steinman's pin or by the adhesive plaster method. There are many cases of fracture of the lower limb requiring simple extension, often for only a short time, which do not necessitate

the complicated mechanism of a Balkan frame. There are several types of pulley which may be fixed to the end of the bed, but all have the disadvantage of being unstable, and of supplying no support to the end of the Thomas's splint and no fixation, which usually has to be achieved by numerous sandbags, boxes, or other unwieldy contrivances. I had the apparatus to be described manufactured by Messrs. Body and Co. of Chelmsford and Southend. It clamps on to any standard hospital bed. A piece of wood splinting is placed across the two horizontal bars, and this supports the end of the Thomas's splint, which can be secured in position by a few turns of cord. When the end of the bed has been raised to allow counter-extension by the weight of the body the height of the pulley can be adjusted to come into line with the Steinman's pin by altering the position of the hook on the vertical bar, which rests on the lower bar of the bed. Once the extension weights have been attached by the usual cord to the Steinman's stirrup, the limb and Thomas's splint require no further attention or adjustment, as the flat wooden support prevents the outward rotation of the foot and the splint which is the bugbear of most methods of lower limb extension. We have six of these supports in use at the Chelmsford Hospital, where a large number of lower limb fractures are dealt with, and have found them satisfactory.

its genetics and others recording the ultimate result of Gray's intratympanic treatment with thyroxine; and there are also papers on many other forms of treatment. H. M. Taylor shows the influence of quinine taken during pregnancy in producing deafness in the child at birth. Brunner writes on disturbance of hearing in brain tumours, a subject that has not been much studied. A remarkable number of papers now report scattered cases of otitic meningitis with recovery, largely due to the use of protosil. Petrositis still receives much attention in the literature.

In the nose and throat section Hetler presents a study of infections of the mucous membranes in relation to nutrition, drawing attention to the importance of the vitamins, especially vitamin C; and Sewall describes removal of the sphenopalatine ganglion by a transantral route. In the subsection on diseases of the bronchi and oesophagus is an outstanding paper by Berk and Harris on the treatment of chronic secreting bronchiectasis by Roentgen therapy. Remarkably good results were obtained in a series of thirty cases. The treatment was based on the analogy of the effect of Roentgen rays in abolishing the secreting capacity of the salivary glands.

GERMAN FOR MEDICAL STUDENTS

German for Students of Medicine and Science. With Notes, Grammatical Introduction and Vocabulary. By W. F. Mainland, M.A. (Pp. 160. 8s. 6d. net.) London and Edinburgh: Oliver and Boyd Limited. 1937.

One of our more accomplished polyglot diplomats was reported the other day as saying that he did not consider that he "knew" a language until he could make an after-dinner speech in it and solve a cross-word puzzle. If students of medicine and science limited their reading to those languages which they "knew" in this sense, their demands upon that modern tower of Babel, the book-stacks of the large medical library, would indeed be modest. But doctors rush in where diplomats fear to tread, and it is with a view to facilitating this rushing-in process that Mr. Mainland has written his book. No claim to originality in conception is made; indeed, in the preface the author admits that between the purely literary and the heavily scientific "eminently successful compromise has been achieved in general science readers by such books as the *Science German Course* of Mr. A. G. Haltenhoff, *Basic German for Science Students* by Dr. M. L. Barker, and the *German Course for Science Students* of Drs. Bithell and Dunstan." But he adds, "The present little volume is a modest attempt to adapt this blend to the use of medical students, without leaving the pure scientists altogether out of account."

The book consists of some preliminary notes on grammar and hints on text reading; these are followed by texts for reading, which are arranged in order of difficulty. Finally there is a vocabulary. With regard to the notes on grammar the criticism immediately arises that, as this is not intended to be a beginner's manual and knowledge of the rudiments of the language is presupposed, such an arbitrary selection of alleged "snags" in German grammar is not needed and is slightly irritating. For instance, surely a knowledge of the rudiments of German implies a knowledge of the difference between *Mann* and *man*.

The vocabulary is presumably intended to save the reader the labour of using a dictionary, and this intent would have been furthered if the translation of the difficult words had been placed immediately after the passage in which they occur. It is arguable that the memory is more lastingly impressed if some labour goes

to the solving of a problem; this used to be a favourite axiom of schoolmasters, but its application to the teaching of more mature minds, with their lower threshold for petty irritants, is of doubtful validity. Perhaps it is such a doubt which has induced Mr. Mainland to compromise.

The texts provided are wide in their interest and well chosen and graded, but it cannot be said that this book marks a great advance in imparting the necessary knowledge of the language to the would-be student of "original papers."

ANALYSIS OF MEDICAMENTS

Drugs and Galenicals: Their Quantitative Analysis. By D. C. Garratt, B.Sc., Ph.D., F.I.C. With a foreword by Sir Frederick Menzies, K.B.E., M.D., LL.D., F.R.C.P. (Pp. 422; 3 figures, 30 tables. 25s. net.) London: Chapman and Hall, Ltd. 1937.

Garratt's *Drugs and Galenicals* deals with a subject so highly specialized that up to recent times there was no textbook which met in any degree the needs of the analyst of medicaments. The methods employed by the few who formerly practised in this sphere varied with different individuals, each analyst having evolved for himself plans of procedure which became trustworthy in his own hands because of his special experience, but which might be a pitfall to others. More recently the methods available for use have become more numerous, more satisfactory, and less dependent for their success on the special experience of the individual. Garratt, having had an extensive practical experience in the analytical examination of medicaments, has been able to make critical trials of the many analytical operations proposed by different workers. His book describes the merits and defects of these, and indicates how they may be used to obtain decisive analytical results. The treatise covers a very extensive range, and each subject is treated with generous wealth of detail. It is commendably well written, having regard to the fact that the matter is one which does not lend itself to good writing. The only thing we observe to be lacking is one which in the present stage of progress is not easy fully to supply—namely, comment on the comparative solubilities of substances in the solvents used for extractive dissolution. Perhaps also a few words might with advantage have been added here and there explaining the theoretical basis of the methods used—as, for instance, in the case of the separation of strychnine from quinine. A remark of this nature would serve as a caution to an inexperienced worker that aqueous hydrochloric acid would not be suitable for the extraction of strychnine from a chloroformic solution. But perfection is a high ideal. The book will supply an urgent need.

SEX AND SOCIETY

Sex in Relation to Society. Being the First English Edition of Volume VI of *Studies in the Psychology of Sex*, abridged and revised. By Havelock Ellis. (Pp. 529. 12s. 6d. net.) London: William Heinemann (Medical Publishers) Ltd. 1937.

This volume is a new edition of the last volume of the author's well-known *Studies in the Psychology of Sex*, which was published for doctors and scientific students only, nearly thirty years ago. The chief difference which may be noted in the interval is not so much in the contents or arrangement of the book itself as in the fact that nowadays a work of this sort may be published for general reading and will be read in all seriousness by a large number of intelligent people, whereas thirty years ago the implication was that if released for general perusal it would have been regarded merely as pornography. So far have we advanced that the problems here

removal of intracranial tumour. Of the amputations the greatest number (154) were through the thigh, and the next greatest (121) amputation of the finger.

Radiotherapeutic Service

The first place in the Medical Supplement is given to an account of the radiotherapeutic clinic at Lambeth Hospital. The number of new cases placed on the records of this clinic increases every year. For various reasons the tables, which occupy fourteen pages, must not be taken as furnishing indications generally applicable in the field of x-ray and radium therapy. For example, all untraced patients are reported and counted as dead—a very big assumption in view of the floating population in the neighbourhood of the clinic—and no patient is said to have died of an intercurrent disease unless a post-mortem examination has been performed and he has been found free from all signs of the malignant disease for which he was treated. With the exception of rodent ulcers and small squamous carcinomata, which are treated by interstitial radium needling or by radium surface appliances, all malignant growths are treated first by external radiation, either by x-ray therapy or by radium surface appliances at 2 or 3 cm. from the skin. Owing to the very large number of cases of malignant disease coming to the clinic only sixty non-malignant cases were treated during the year, though it is felt that there must be a very large number of such conditions which would benefit by radiotherapy and for which at present no provision is made. The same hospital has a radium centre for carcinoma of the uterus, where 104 cases were treated during the year, most of them in an advanced stage of the disease.

In the plastic surgery unit at St. James Hospital 294 cases were admitted and 397 operations performed, including eighty-two Thiersch grafts. There is also a speech-training department here for patients suffering from some abnormality of speech mechanism, and it is suggested that the use of this department for postgraduate teaching might be increased. At the goitre clinic at New End Hospital 134 operations were performed, followed by considerable improvement in eighty and some improvement in twenty-nine. The arthritic unit at St. Stephen's Hospital has been the scene of some research work on the determination of vitamin C reserves and also the use of gold salts in rheumatoid arthritis. Certain clinical observations have been made on the use of insulin in selected cases of this complaint, and it is said that some of the results have already proved very striking. Notes are given of the work at two diabetic clinics, at St. George's-in-the-East and St. Peter's, and some cases are described illustrating the action of protamine-insulin and zinc-protamine-insulin, compared with that of ordinary insulin. The need for caution in the initial stages of treatment with protamine is emphasized.

Special Subjects and Unusual Cases

Among several reports on special subjects there is one on antitoxin therapy in diphtheria. Opinion generally is said to be crystallizing that doses in excess of 100,000 units, especially when all or part is injected intravenously, are not required. The prevalence of cerebrospinal fever in London has recently increased. During 1936 there were ninety-nine cases, and during six months of 1937 108 cases. There is a tendency at the five Council hospitals where these cases are treated to supplement or replace by other methods the standard Flexner method of intrathecal serum treatment. The treatment of cerebrospinal fever is entering upon a new phase, at present transitional.

Prontosil in the treatment of erysipelas is regarded as an agent exercising a specific control in this condition. An interesting chapter on the Council's rheumatism scheme, for which at present 650 beds for acute and subacute cases and 250 for convalescent cases are provided, is included in the report. It is considered that London can

be well satisfied with the progress made during the last nine years. A scheme, probably the most comprehensive of its kind in existence, has been worked out for dealing with the problem of juvenile rheumatism and its sequels. It provides facilities for early diagnosis, an adequate period of institutional treatment, arrangements for the education of the convalescent child, and the constant medical supervision of every rheumatic child up to and after leaving school.

Only a brief glance can be given at the several papers contributed by the medical officers of the Council on interesting and unusual cases.

These include two cases of agranulocytic angina, certified to be suffering from faucial diphtheria and sent to a fever hospital; a case of leuco-erythroblastic anaemia associated with a teratoma: an unusual case of aplastic anaemia in which there was great difficulty in making the diagnosis during life; two cases of paratyphoid fever with rare complications, staphylococcal pyaemia in one instance and terminal *B. paratyphosus* B meningitis in the other; two cases of solitary non-parasitic liver abscess presenting no indication of how or whence infection came; a case of aneurysm associated with tabes dorsalis which was treated by distal ligation, the patient improving considerably; and a fatal case of pellagra in a Deptford woman who had never been out of England, but who had a history of diet poor in animal protein and almost certainly deficient in vitamins. One case of conjoined twins is reported. The twins, one of which lived for twenty-four and the other for thirty hours, were united brow to brow. The most remarkable point in the case is that the first-born twin was apparently born dead, but when the circulation of the second twin became brisk the first-born began to breathe.

Cost of the Service

The cost of all these services is the subject-matter of a separate publication in which those interested in hospital administration, voluntary or municipal, will find much useful material. Municipal hospital expenditure is increasing not only in the aggregate but also in the amount spent per patient. In the general hospitals for acute cases—referred to in the report as "acute hospitals," not a very happy term—under the administration of the London County Council the average weekly cost of maintenance per patient has gone up by 12s. during the last five years and now reaches £3 19s. 4d. per patient. It should be understood, however, that this is the mean figure of all the hospitals in this category, and there are some rather wide variations between them. Thus the average cost of maintenance at Hammersmith Hospital, South Block, where the British Postgraduate Medical School is situated, is as much as £6 3s. 1d., while at St. James, Balham, it is only £3 6s. 3d. The cost lessens, of course, with the size of the hospital. Thus St. James has 900 beds commonly available, and Hammersmith, South Block, only 400.

The cost tables are more detailed in form than those given in the annual reports of King Edward's Hospital Fund in respect of the voluntary hospitals. They are based upon the assembling into groups according to the type of patient treated. In the general hospitals for acute cases, which are most similar to the large general voluntary hospitals, the medical service represents a cost on the average of 4s. 5d. per patient per week, and the nursing service 10s. In the general hospitals for the treatment of chronic cases the total cost of maintenance is £2 4s. 1d., and in the fever hospitals £4 12s. 3d., of which the cost of the medical service represents just upon 4s. and of the nursing service 12s. 6d. In the tuberculosis hospitals, with a total weekly cost per patient of £3 15s. 9d., the medical services cost 4s. 8d. and the nursing services 6s. 8d.

A word should be added in praise of the orderly presentation of these reports. Details are given in a form, tabular or otherwise, which makes it a simple matter to elicit any desired information.

LONDON'S COUNCIL HOSPITALS

A GREAT ADMINISTRATIVE ACHIEVEMENT

The London County Council administers the most extensive hospital service in the world. In its seventy-five general and special hospitals it could put to bed the entire population of a town like Kingston-on-Thames or Richmond or Twickenham. The total accommodation of its general hospitals alone is four times that of the twelve great teaching hospitals of London. It is an extending service, upon which five and a half million pounds a year is spent, this sum having gone up by one million during the last five years. The work is summarized from various aspects in three of the familiar orange-coloured fasciculi forming parts of the annual report of the Council itself.¹

New Developments

A large programme of modernization and extension was begun in 1931 and is still continuing. Among the larger schemes completed during the year under review were a new ward block containing just upon 100 beds at Lambeth Hospital, new x-ray departments at three hospitals, massage departments at two, and nurses' homes at two, one of them with 200 bedrooms and the other with 120. In the fever hospitals schemes for new isolation blocks and other reconstructions are in progress or just completed. In a number of the general hospitals special units have been established for branches of medical and surgical work of such a specialized nature that it is not economical or convenient to provide for it at every hospital. The latest to be added are units for the treatment of patients with foreign bodies in the air or upper food passages and for the surgical treatment of cardiovascular disease. At the latter, which is situated at Lambeth Hospital, eleven patients received surgical treatment during the period covered. Seven cases of cardiac ischaemia were investigated, and in four the operation of cardio-omentopexy, devised by Mr. L. O'Shaughnessy, was performed successfully by him.

The question of improving the treatment of fracture cases has been considered. The arrangements in the Council's hospitals for the treatment of fractures conform in general with the principles laid down in the report of the British Medical Association committee. The L.C.C. is following the general policy of concentrating fracture cases in selected hospitals. The same policy of concentration is being followed with regard to epileptic patients. As few epileptic patients as possible are retained in public assistance institutions, and with the exception of a few persons subject to slight and infrequent fits all epileptics are accommodated in sick wards or transferred as soon as possible to one or two particular hospitals. In the seven group laboratories of the pathological service the examinations of specimens during the year numbered not far short of a quarter of a million, and at the Belmont central laboratories, which were built by the Metropolitan Asylums Board mainly for the production of diphtheria antitoxin, the actual volumes of diphtheria antitoxin and of streptococcus antitoxin (scarlatina) issued during the year amounted to 153 and 248 litres respectively. It may be added that in connexion with medical education sixteen of the Council's general hospitals have now been recognized by the Royal College of Surgeons of England for the candidature of members of the staff for the final Fellowship examination of the College, and thirteen hospitals by the British College of Obstetricians and Gynaecologists for its diploma.

Maternal Welfare

In the maternity departments of the Council's hospitals it was necessary to make provision for nearly 2,700 more

births in the year under review than in the year before. The number of births in these hospitals was over 18,000. Attendances at the ante-natal clinics went up to 120,500 from 97,800 the year before, and it is stated that only a very small percentage of London women now receive no ante-natal care at all. The number of maternity patients who return for a post-natal examination is also increasing, though more slowly. The rate of maternal mortality in the Council's hospitals shows a sharp decrease. It has fallen by more than one-half (from 7.2 to 3.5) in three years. The fall in the number of deaths from abortion (nineteen in 1936 as against fifty in 1935) reflects the greater care in the diagnosis of septic abortion. A large number of seriously ill patients are now admitted to the North-Western Hospital puerperal fever unit, where 185 cases were treated during the year—151 of uterine sepsis and associated complications and thirty-four of other diseases. The deaths numbered thirteen in the first category and one in the second.

In the Medical Supplement Dr. Letitia Fairfield gives some further details. The number of women confined in the Council's hospitals during the year was 17,936, more than twice the number which obtained in 1929. Of this number 16,302 had had ante-natal care at an L.C.C. clinic, and among these there were thirty-two deaths; among the remaining 1,634 who had had ante-natal care from other sources or had had none at all there were thirty-one deaths. But such figures have to be interpreted with caution, because many emergency cases are sent to hospital during labour because they are abnormal, but they are not necessarily abnormal because they did not have ante-natal care. Three of the deaths were associated with anaesthesia, but in every instance the anaesthetic was given by an experienced medical officer and in the opinion of the consultant obstetrician to the unit was properly chosen. No mishap occurred in connexion with the scheme permitting the administration of light intermittent anaesthesia by midwives.

Statistical Tables

The statistical tables, which in Part I of the report number over sixty, afford a great amount of interesting information. One table shows the number of cases admitted to the special hospitals in which the disease finally diagnosed differed from that stated on the admission certificate. Thus three cases certified on admission as dysentery turned out to be chicken-pox; thirty-seven admitted as diphtheria turned out to be measles; four admitted as measles proved to be diphtheria; and fifteen admitted as chicken-pox proved to be measles. Over 1,700 cases were admitted with a mistaken diagnosis of diphtheria, 1,016 with a mistaken diagnosis of scarlet fever, and 976 certified on admission to be measles proved to be some other condition.

The ages of patients in the fever hospitals are interesting. During the year there were admitted 136 cases of scarlet fever, forty-six of diphtheria, and fifteen of measles in which the patients were over 40 years of age. The sex incidence shows all the infectious diseases, except measles, to be heavier among females.

The figures also show how the out-patient service of the general hospitals is being developed. Out-patient treatment is now provided at twenty-five such hospitals at a cost of £60,000, and during the year the number of patients seen in these departments was 141,000, an increase of 30,000 on the year before. The number of operations carried out at the general hospitals was just over 40,000. The greatest number were done for appendicitis (3,929). There were 2,564 cases of curettage of the uterus, 2,963 manipulations in fractures, and 3,056 incisions for abscess under general anaesthesia. Seven operations were done for excision of a myeloma, seven periarterial sympathectomies, eight operations for epithelioma of the lip, six operations on the ovaries and Fallopian tubes for malignant disease, and three for

¹ London County Council. *Annual Report of the Council, 1936*. Vol. IV, Public Health. (Part I) General and Special Hospitals (2s. 6d.); (Part II) Hospital Finance (1s.); (Part III) Medical Supplement to the Report on the Hospital Services (5s.). Westminster: P. S. King and Son, Ltd.

majority of medical men. The number of offences for which a sentence of corporal punishment can now be given is surprisingly large. Its administration for living on the earnings of a prostitute and for robbery with violence is comparatively recent. Few persons except specialists in this branch of legal research can have known that a section in the Diplomatic Privileges Act, 1708, permits corporal punishment for a solicitor who serves a writ on a foreign ambassador, and that an Act of 1786 gives power to award it for certain irregularities in the slaughtering of horses and cattle. The committee, of course, recommends the repeal of these inappropriate provisions, but in forming its opinion on the use of corporal punishment for various other offences it has paid close attention to the views of medical men and psychologists. In recommending the abolition of birching for young offenders the committee draws a wise distinction between a beating by a parent or master, with whom the child has some constructive relationship, and an impersonal judicial birching by a police officer, usually after a considerable delay. The section of the report dealing with this matter is a model of reasoned argument, and lays great stress on constructive means of dealing with young offenders. If birching is abolished the committee recommends that the juvenile courts should be given additional powers to enable them to deal with those offences which merely require an effective deterrent.

It so happens that the committee's report appears soon after a notorious case, in which the infliction of sentences of flogging on two criminals received wide and unsavoury publicity. The report, if it receives proper notice, will do much to correct the wild statements that have been made about the practice in the infliction of this punishment. Judicial flogging is a severe penalty, but not as frightful as some newspapers have represented it. The medical safeguards prevent its being applied to a prisoner who is not physically capable of standing it, but do not ensure that it shall be withheld from a prisoner whose mind and disposition make it an unsuitable form of punishment. The committee found that in large numbers of cases it will have no marked effect on the offender's frame of mind and that in some rare cases it may have a salutary effect in compelling him to face the realities of his offence. It was satisfied, however, that in other cases it might do lasting damage to a man's character and personality. In the words of one experienced witness, corporal punishment occasionally hardens the outlook of a tough-minded offender, and may perhaps occasionally do harm to some who are tender-minded; and there appears to be a risk that it may sometimes produce a result that is not intended. A weighty reason against it

is that it has no reformatory quality. The committee therefore considers that its retention can only be justified if it can be shown to be essential in the interests of the community as a deterrent. None of the witnesses suggested that corporal punishment restrains the offender from all forms of crime, and even those who believed most strongly in its deterrent effect claimed only that it deterred him from the special offences for which corporal punishment may be given. The results of a detailed analysis lent support to the view that it was apt to produce feelings of resentment and bitterness which make an offender more likely to commit other offences. The committee was unable to find any body of facts or figures which showed that the *ad hoc* introduction of a power of flogging had brought about a decrease in the number of the offences for which it might be imposed, or that such offences had tended to increase or decrease in proportion to the number of floggings ordered. It therefore recommends the repeal of all powers to punish indictable offences with flogging. It is particularly interesting that the committee should have done so in the face of the opinion of the judges of the King's Bench Division that flogging was a useful deterrent and might well be retained for a number of the offences for which it may at present be ordered. The committee felt that if it were to be retained the confused and miscellaneous provisions of the existing law must be swept away and a new system built up on some more logical principle. The only suggestion made during the hearing of evidence was that it should be reserved for cases in which gross and brutal violence had been used, and this suggestion was ultimately based not on the view that the offenders could not be effectively deterred by other methods but on the argument that violence must be met by violence. The committee quotes with approval the words of Mr. Asquith in 1900, that nothing more repugnant to the most elementary principles of justice and common sense could be imagined than to say that because a man has committed a savage offence those whose duty it is to enforce respect for the law should begin that man's punishment with correspondingly savage treatment. The only remaining use which the committee could find for corporal punishment is in deterring violent prisoners from assaulting prison officers, and it has concluded that flogging cannot yet be safely abandoned as a prison punishment; it should, however, continue to be used very sparingly, and the hope is expressed that in course of time it may be dispensed with altogether.

The most valuable feature of the report is its objectivity, and the complete absence from it of any trace of sentimentality. The next step is for

SATURDAY MARCH 26 1938

THE CHEMICAL BASIS OF URAEMIA

Last week's meeting of the Medical Society of London was devoted to a general discussion on uraemia in its medical, surgical, and biochemical aspects; a report of the speeches appears at p. 693. All experimental work during recent years has been in the direction of showing that the symptoms of uraemia are caused not by the retention of any one chemical substance but by variations in the relative amounts of several substances in the tissue fluids. These variations may differ considerably from one case to another. Thus retention of inorganic phosphate together with diminution in ionized calcium tends to cause muscular irritability, whereas the retention of phenols will cause weakness and apathy. The very diversity of the symptoms does, in fact, suggest that more than one factor is at work, and that there are some cases in which stimulation of the nervous system is the more striking phenomenon and others in which depression is more obvious. Animal experiments have shown that the intracisternal injection of certain electrolytes into the cerebrospinal fluid may cause a rise of blood pressure with muscular twitching and disturbances of breathing. The similarity of these symptoms to those of uraemia has prompted M. F. Mason and others¹ to investigate further the changes in the chemistry of the cerebrospinal fluid in experimental uraemia produced by bilateral nephrectomy, ureteral ligation, or ligation of the renal arteries. The resulting symptoms were weakness and vomiting with transient and inconstant changes in blood pressure, followed by muscular irritability and later by stupor. Convulsions and coma were rare. As a rule muscular irritability occurs at the time when diminished calcium and increased phosphate can be detected in the cerebrospinal fluid and seems to depend more closely upon changes in the fluid than in the blood plasma. The same was observed in patients with uraemia; but in both patients and animals the results were not constant, and in the later stages depression may be observed despite pronounced changes in the levels of calcium and phosphorus. Phenols when injected intravenously produced weakness, apathy, and ataxia, and if given

before the intracisternal injections inhibit the muscular twitching and respiratory symptoms. The phenol content of the blood and body fluids rises in experimental uraemia. Experimentally guanidine gives rise to apathy, vomiting, ataxia and tremor, muscular twitching, and convulsions. Big doses produce a semi-comatose state. Guanidine is increased in the blood in clinical and experimental uraemia and behaves as an antagonist to calcium.

Commenting on their results the authors feel that they are justified in drawing certain conclusions as to the nature of the chemical factors in uraemia. "Central" deficit of calcium ions (that is, in the cerebrospinal fluid rather than in the blood) appears to be an important cause of neuro-muscular irritability, and this may also play a part in the production of respiratory disturbances. These symptoms may in some cases be further evoked by the accumulation of guanidine. Guanidine can, however, also bring about symptoms of depression, and may account for vomiting and other gastrointestinal symptoms. Accumulation of phenol derivatives has an action antagonistic to that of calcium deficiency, inhibiting muscular excitability and causing weakness, apathy, stupor, and coma. In certain instances dehydration, acidosis, and chloride deficiency may be important factors, but probably not essential features of the uraemic syndrome. The clinical manifestations of uraemia therefore appear to result from a variety of chemical disturbances, and the symptoms exhibited by any particular patient will depend upon which of these disturbances is especially in evidence. This in turn will depend upon such factors as diet, the state of the gastro-intestinal system, and the rapidity with which renal failure has developed. In no experimental study of uraemia has any definite relation between chemistry and blood pressure been traced, and it is known that uraemia may occur in patients with normal or low blood pressure. The height of the blood pressure seems to depend more upon the pathological state of the kidney than upon its functional efficiency.

CORPORAL PUNISHMENT

The report of the Departmental Committee on Corporal Punishment, which has just been published,¹ puts the case against corporal punishment more effectively than any argument that has hitherto appeared. In recommending the abolition of this penalty as a judicial sentence the committee substantially agrees with the views expressed in these columns,² which commend themselves to a large

¹ Cmd. 5684. 1938, London, H.M. Stationery Office. (2s. 6d.)
² *British Medical Journal*, 1937, 1, 618.

¹ *Arch. intern. Med.*, 1937, 60, 312.

At the end of ten weeks the weight and height increase among the boys in the milk-fed group was manifestly greater than in those of the biscuit-fed group. Among the girls the increase in height, but not in weight, was manifestly greater in the milk-fed group. These experiments demonstrate the benefit that results from giving a ration of skimmed milk to school children who are receiving an inadequate or unbalanced dietary in their homes. The cost in the second experiment of supplying a child daily with 8 oz. of skimmed milk reconstituted from powder was 12 annas a month, or in our currency less than a halfpenny a day.

THE NEUROLOGICAL FACTOR IN OSTEO-ARTHRITIS

It appears that nervous influences play a part in the causation of the changes in the hip-joint in osteo-arthritis. Eloesser¹ found that changes similar to those occurring in Charcot's arthropathy took place in the joints of animals in which the lumbo-sacral nerve roots had been divided if they afterwards led an active life. Corbin,² continuing observations along these lines at Stanford University, studied the effect of lumbar sympathectomy and section of the lumbo-sacral dorsal nerve roots in cats. He observed that in animals which did not move about freely after deafferentation there were no changes in x-ray appearances, but microscopical examination revealed superficial erosion of the articular cartilage and fibrillation. There was no sclerosis of the spongiosa. On the other hand, when movement was free there was well-marked fraying of the synovial membrane, thickening of the capsule, and enlargement of the head of the bone and the acetabular fossa. The effect of the operation was such that the affected limb was carried in an abnormal position owing to interference with the proprioceptive mechanism, and parts of the joint underwent wear and tear that did not occur under normal conditions. In addition hypermobility resulted and led to further wear; excessive reaction was caused—much increase in the density of the head and neck of the femur, flattening of the weight-bearing area, and thickening of the head of the bone. The ligamentum teres was destroyed in all cases in which there was pronounced general alteration in the joint. Appearances in the bone beneath the calcified articular cartilage suggested that eburnation is at least in some degree a functional response which does not require removal of the cartilage and direct mechanical stimulation. It is clear from Pearson's work³ that degenerative changes take place in the posterior root fibres in advancing years, with loss of sensibility. The ability to perceive vibratory stimuli diminishes more rapidly after the fifth decade and may be completely lost. This is attributed to arteriosclerosis in the spinal cord, especially in the column of Goll, the blood supply of this area being somewhat inefficient. It has long been believed that the changes in osteo-arthritis of the hip were due in some measure to arteriosclerosis, but the

locality of this was thought to be in the bone itself, though there was no correlation between the extent of change in the joint and the degree of arteriosclerosis (Keefer and Myers). Other features of the disease are more readily explained if the circulatory defect lies in the cord. Among these is the variability in the degree of pain in this form of arthritis. Keefer found that only about 7 per cent. of his patients with hypertrophic arthritis suffered from pain. Corbin quotes Hinsey's observation⁴ that the skin temperature was lowered in "deafferented" cats, and suggests that the reduced peripheral skin temperature of arthritic patients is the result of a decreased sensory supply to the limbs. Half a century ago many held that rheumatoid arthritis was due to changes in the spinal cord. This view has been abandoned, but it is interesting to find so much evidence of the part played by nervous influences in the production of osteo-arthritis. In exhaustive studies on the effect of wear on joint structures, chiefly on the shoulder-joint, A. W. Meyer⁵ has, however, shown that extensive destructive changes may occur in the absence of inflammation and without any evidence of nervous disturbances.

SODIUM LACTATE FOR DIABETIC COMA

Before the introduction of insulin into diabetic therapeutics recovery from diabetic coma was an event of such rarity as to excite wonder. Since the introduction of insulin recovery is so confidently expected that death, when it occurs, is disconcerting. It is now generally accepted that the prognosis in diabetic coma becomes worse with increasing age of the patient and with the duration of coma, and that the prognosis is excellent in young patients. As a consequence the view is widely held that the present methods of treating diabetic coma are adequate in uncomplicated cases and fail only in patients who either are weakened by old age or are practically moribund when they first come under treatment. An examination of the published reports of the results of treatment in series of coma cases, however, casts some doubt on this optimistic view, for there is evidence that despite careful treatment unexpected death not infrequently occurs in young comatose diabetics. It would therefore appear that there is still scope for improving our treatment of diabetic coma, and in this respect the use of sodium lactate deserves serious consideration. In 1935 Hartmann⁶ reported the results of treating cases of diabetic coma by three different methods. The first group of cases was treated by insulin and glucose; the second by insulin, glucose, and sodium bicarbonate; and the third by insulin, glucose, and racemic sodium lactate. In Hartmann's opinion the results in the third group were considerably better than in either the first or the second. On examination of his reports in detail, however, it appears that this favourable opinion of sodium lactate is supported not so much by striking clinical results as by the fact that this substance produces a rapid replenishment of the depleted alkali reserve in these cases. This

the Home Secretary to introduce into Parliament legislation which will carry its recommendations into effect, and there is fortunately good reason to suppose that Sir Samuel Hoare intends to do this. If the substance of the recommendations becomes a part of the law of this country it will mark an important step towards replacing the primitive feeling, which still disfigures our penal system, by sound reason based on experience.

CANCER OF THE LUNG

Cancer of the lung has of late claimed increasing attention in several of its aspects. There is in the first place the very debatable question of how the much greater apparent frequency of the disease has come about. Allowing for the effects of longer life and better diagnosis, is there still evidence that lung cancer is becoming more common? It is difficult to estimate, and possibly to overestimate, the effect of modern diagnostic methods, and cases not so investigated may still be supposed to have died simply of bronchitis and heart failure; this was probably the rule rather than the exception in the past. A recent statistical survey by Stocks has led only to the conclusion that the trend of the true frequency of lung cancer will only be ascertainable when present methods of analysis can be applied to the data of a further decade. Another major question is occupational incidence—one aspect of the complex problem of aetiology. Apart from curiosities such as the Schneeberg miners' cancer there has been little positive information from this direction, and it has always to be remembered that occupational descriptions may be highly misleading. Not only may one term cover a multitude of varying circumstances but account has to be taken of the time factor, and unrecorded changes in occupation during a preceding period of many years may wholly vitiate the significance of such descriptions. Furthermore, if road dust is to be accorded the importance to which experiment seems to entitle it, the degree of exposure to this influence determined by the position of dwellings and many other factors may well be of an importance equal to that of occupation itself. The recent examination of 18,280 death certificates in cases of lung cancer by Kennaway and Kennaway suggests that certain classes of worker are especially liable to lung cancer; these are road workers, metal grinders, gasworks employees, and those engaged in the tobacco trade. A third aspect of this subject which is claiming attention is the experimental study of lung cancer. An adenoma of the lung which sometimes exhibits malignant characters is a tumour which naturally appears in mice, and several investigators have studied the effects of known or suspected carcinogenic agents on the incidence of this tumour. The principal experiments of this kind dealing with naturally occurring suspected agents have been those of J. A. Campbell,¹ whose recent paper not only summarizes his own work but furnishes a comprehensive

review of the several aspects of the subject mentioned here. His method has been to expose mice to irritants by inhalation for short individual periods over a long total space of time. The effect of this treatment was negative in the case of exhaust gases from a petrol engine, doubtful in the case of tobacco, but striking when the substance used was dust from the sweepings of tarred roads; 74 per cent. of mice exposed to this dust developed lung tumours, the frequency in controls being 14 per cent. When the dust had been extracted with benzene to remove the tar 45 per cent. of exposed mice still developed tumours, lending some apparent support to the otherwise very debatable proposition that the inhalation of silica predisposes to lung cancer. The significance of these results is of course wholly dependent on whether these lung tumours in mice can be considered analogous to lung cancer in man. Campbell adheres strongly to the view that they can, but the wide dissimilarity in structure and behaviour between the mouse and human growths, and the remarkable frequency of lung growths in mice kept under what are usually considered healthy conditions, seem to call for some caution in the interpretation of these results.

SKIMMED MILK FOR SCHOOL CHILDREN

The more extensive use of skimmed (separated) milk has been advocated by the Technical Commission on Nutrition of the League of Nations Health Organization. Large quantities of this type of milk are available at butter factories at a very low price. Since it contains the nitrogen, carbohydrate, and mineral fractions of the milk, it has a high nutritive value for human beings. The difficulty, as pointed out in another report of the League,¹ consists largely in distribution. By the time the skimmed milk has been brought to the towns, pasteurized, and bottled, its price, so far as calorie value is concerned, will be very much the same as that of whole milk. An alternative method was therefore suggested of supplying the separated milk in dried form. It is interesting to note that observations are already available to prove the value of this method. Aykroyd and Krishnan² in India found that the addition of liquid skimmed milk reconstituted from powder to the diet of children in residential hostels brought about an acceleration in growth and a decided improvement in general condition. In a more recent paper Krishnan and Mitra³ report two experiments made on children of the poorer classes in Madras. In the first experiment twenty boys were given daily 8 oz. of liquid skimmed milk for three months, while twenty similar boys received no addition to their diet. The average increase in both weight and height was notably greater in the former than in the latter group. In the second experiment twenty-four boys and eighteen girls were given daily 8 oz. of skimmed milk reconstituted from powder, while a similar number of boys and girls were given 1 oz. of wheat-flour biscuit of about the same calorie value.

SURGICAL PROCEDURES IN GENERAL PRACTICE

This is one of a series of articles contributed by invitation

SCALP WOUNDS AND FRACTURES OF THE SKULL

BY

LAMBERT ROGERS, M.Sc., F.R.C.S., F.R.C.S.Ed.,
F.R.A.C.S., F.A.C.S.

It has often been said that in cases of head injury it is the condition of the brain which really matters, while that of the integuments is of relatively minor significance. Although the truth of this statement is undoubted it must not be regarded as a reason for minimizing the importance of scalp wounds and skull fractures. It is my object in this paper to concentrate upon these lesions, leaving the question of the degree of damage to the brain and its treatment for consideration in the next article. It will be realized, however, that the conditions are so often associated that treatment is frequently required for damage to the intracranial contents as well as to their envelopes.

Scalp Wounds: Some Anatomical Considerations

The scalp is characterized by its extreme vascularity and relative insensitivity. Many of us have experienced a trickle of blood running over the face from a scalp wound which, because of its painlessness, we were unaware had taken place. Haemorrhage from the scalp is profuse on account both of the number of vessels and of the fact that they lie in the dense subcutaneous connective tissue and are thereby prevented from retracting when divided. The blood supply of this region is so rich that even in extensive injuries, such as partial avulsion, there is very little risk of tissue necrosis, and it is well known that because of its vascularity incisions may be made in the scalp with impunity in any direction.

The most important layer of the scalp, considered from the surgical aspect, is the subaponeurotic lymph space, which lies beneath the epicranial aponeurosis (galea aponeurotica), separating it from the pericranium. Because of this space the scalp is free to move on the skull. Effusions may collect within it, and because of venous connexions (emissaries) with the intracranial venous sinuses an intracranial spread of infection may result; hence this space is termed the *dangerous area of the scalp*. The epicranial aponeurosis is attached posteriorly to the linea suprema of the occipital bone and on either side to the zygoma, but in front it is unattached to the frontal bone, so that while subaponeurotic effusions are prevented from spreading into the neck or the temporal fossa, they readily extend anteriorly into the loose tissue of the eyelids.

Treatment of Scalp Wounds

The treatment of an injury to the scalp may constitute a relatively minor part of the management of a case of head injury, but it may be the all-important part, and many scalp wounds are the result of a comparatively slight blow, which has not been sufficient to concussion the patient or damage the brain. Scalp wounds are generally of the contused or lacerated variety, less often of the incised or punctured type. There is usually a good deal of matting of hair from coagulated blood, and this should first be cut away and shaved from the edges of the wound, which may then be the better examined.

If a main vessel such as the superficial temporal artery has been divided and is bleeding it should be secured with a catgut ligature, which may need to be passed on a needle. If the margins of the wound are bleeding freely, haemorrhage may be controlled either by the pressure of an assistant's fingers along the wound edge or by applying a series of artery forceps to the cut edges of the epicranial aponeurosis and drawing this outwards over the wound. Mattress sutures along the edges of scalp wounds are apt to introduce infection, but a troublesome bleeding point may in emergency be secured by means of a mattress suture passed down to the bone. Where possible, the underlying bone must be carefully examined by inspection and, if necessary, by the use of a probe to ascertain if a fracture is present; because if there is one we are no longer dealing with an uncomplicated scalp wound, but with a case of compound fracture of the skull, treatment of which is urgent and is considered under a separate heading.

Except for the most trivial cases, and but few even of these, scalp wounds almost always extend into the dangerous subaponeurotic area. Once haemorrhage has been arrested, therefore, and it has been ascertained that the bone is undamaged, our object must be to protect the patient from the dangers of infection and to try to promote healing of the wound by first intention. For these reasons scalp wounds should be treated as emergencies as soon after their infliction as possible. The edges must be cleaned well with soap and water, and if bruised, irregular, and dirty, excised with a sharp scalpel and approximated with a series of interrupted fine silkworm-gut sutures passed on a curved cutting needle through the whole thickness of the scalp on either side. A dressing of gauze wrung out of spirit is then applied, and if healing occurs per primam the sutures may be cut on the fifth or sixth day and removed a day or two later. If infection and suppuration ensue the wound must be opened and drained at once to allow free egress of the products of infection from the dangerous area, for the possibility of an intracranial spread of infection by emissary veins has always to be kept in mind. It was because of this that Percival Pott wrote of the scalp: "This though it be called the common tegument of the head, yet injuries to it become of much more consequence than the same kind of ills inflicted on the common teguments of the rest of the body." Owing to the extreme vascularity of the scalp, however, infection is unusual, and in most cases healing of scalp wounds is both rapid and uncomplicated.

Fractures of the Skull

It has long been realized that extensive fractures may occur with very little apparent damage to the brain, while, on the other hand, serious intracranial complications may result from head injuries in which the skull has not been fractured. In none of four cases of traumatic intracranial haemorrhage requiring craniotomy which I have recently reported was the skull fractured (Rogers, 1937). Fractures of the skull, like fractures in general, may be the result of direct or indirect violence. In the former case they tend to radiate from the point of impact of a localized blow delivered to the head, while in the latter they may result from such an injury as a fall from a

result is to be expected, for the rationale of giving sodium lactate is that the lactate group is changed into glycogen in the liver and thus liberates an equivalent quantity of the base, sodium, which is available to counteract the acidosis. Joslin and his collaborators⁷ have criticized Hartmann's results, but it is only fair to point out that their criticism is based, not on a trial of Hartmann's methods, but on the belief that their own results are as good as they could hope. Recently Wood and Bryer⁸ have reported a case of severe diabetic coma in which treatment with insulin and glucose seemed to have little effect but in which the administration of sodium lactate led to decided improvement. These authors followed Hartmann's technique, slowly injecting a 1/6 molar solution of sodium lactate intravenously until a total of 60 c.cm. per kilogramme of body weight had been given. It is true that this report concerns only one case, but it was one of such severity, and the onset of clinical improvement seemed to be so definitely correlated with the administration of lactate, that the favourable result is noteworthy. Much further experience will have to be gained before the value of sodium lactate as an adjunct to the treatment of diabetic coma with glucose and insulin is established, but the results already obtained are sufficiently promising, and the possibility of harmful effects from the administration of sodium lactate by Hartmann's technique sufficiently small, to permit this newer method of treating severe cases of diabetic coma to be given adequate clinical trial.

REPAIRING DAMAGED GOODS

The results of an international inquiry into measures for rehabilitation of prostitutes are published by the League of Nations Secretariat as one of a series of pamphlets on Social Services and Venereal Diseases.⁹ Replies from over forty countries to a questionnaire show that the need for cheap medical treatment for venereal disease is now widely recognized. In some countries such treatment is compulsory by law for all sufferers, and, as regulated prostitution declines, this group of countries, already the largest, recruits new members; in others it is only compulsory for prostitutes; and in eight countries, including our own, treatment, though voluntary, is encouraged by facilities organized or subsidized by the State and by propaganda and instruction. There is not the same wide recognition of the need for social help, and the number of countries where social service is combined with treatment at venereal disease clinics and hospitals is still small. An account is given of the systems at work in two of the countries which rely on individual social assistance—the United Kingdom and France. In the former country the hospital almoner acts as a link between the patients and the social and charitable institutions which might be useful to them; there are hostels attached to the public hospitals in London

where women recommended by the treatment centres receive free or cheap board and lodging and some general education and training in work and are helped to find employment when they leave; and help is also given through training in hospitals. In France the patients are helped by workers attached to hospitals as social assistants. Other countries, such as the Union of Soviet Socialist Republics, have set up special institutions for combined medical and social treatment. The report suggests lines for future planning and should prove of value to social workers in all countries.

MEDICAL OFFICERS FOR THE REGULAR ARMY

It is satisfactory to learn that the supply of medical officers for the Regular Army is being maintained at a rate which should soon make up for the shortage experienced for some years after the war. Since 1934, when the recommendations of the Warren Fisher Committee were adopted, 195 short service commissions have been given. Of this number 182 qualified in home medical schools and thirteen in the Dominions. Resident civil hospital appointments were held by 152 officers before or after their being gazetted to commissions. This high proportion is the result of seconding young officers to complete or to take up house appointments after being gazetted into the Royal Army Medical Corps. Since 1935 junior officers with special qualifications or who have experience beyond the average in particular branches of medicine may be "graded" for special employment in the subject of their choice, and while so employed receive additional pay. Up to date forty-nine have been "graded" as follows: surgeons, 19; anaesthetists, 10; gynaecologists, 6; physicians, 5; pathologists, 3; otologists, 2; ophthalmologists, 2; dermatologists, 2.

The twenty new Fellows of the Royal Society elected on March 17 include C. H. Best, M.D., Professor of Physiology, University of Toronto; J. W. Cook, D.Sc., Professor of Chemistry, Research Institute, Royal Cancer Hospital, London; W. E. Gye, M.D., Director of Laboratories of the Imperial Cancer Research Fund; Julian S. Huxley, D.Sc., Secretary of the Zoological Society of London; K. M. Smith, D.Sc., Senior Research Assistant, Plant Virus Station, Cambridge; E. Stedman, D.Sc., Lecturer in Department of Chemistry in Relation to Medicine, University of Edinburgh; and H. H. Woollard, M.D., Professor of Anatomy, University College, London.

The annual meeting of the Royal Medical Benevolent Fund will be held at 11, Chandos Street, W., on Tuesday, April 5, at 5 p.m., when the financial statement for the year ended December 31, 1937, will be presented and the officers and committee for the current year elected.

⁹ Allen and Unwin, price 1s. 3d.

Importance of Radiography

All cases of head injury should be radiographed (Rogers, 1933), when possible. Clinical examination alone may fail to find a depressed fracture, especially if this is in the temporal fossa, beneath the temporal fascia rendered tense by blood-clot. To reveal such a fracture a series of plates may be required, with a different degree of rotation of the skull shown on each. Fractures must be differentiated from the grooves for the meningeal vessels. These grooves are sometimes abnormally deep and well developed. Their position will usually serve for recognition, since linear fractures tend to be horizontal rather than vertical.

Anaesthesia

Provided it is not introduced by passing the needle through infected tissue, thereby risking the spread of infection, local analgesia may be used, the whole operation site being surrounded by an area infiltrated with procaine hydrochloride (1 per cent.) or novocain (1 per cent.) to which adrenaline (1 in 100,000) has been added. As much as 200 c.c.m. or more of this solution may be used without ill effects.

When the patient is quiet and unconscious no anaesthetic whatever is needed, while if he is irritable and restless it is usually advisable to employ general anaesthesia; and if the services of an expert anaesthetist are available, nitrous oxide, oxygen, and chloroform form a useful combination. Ether may be used; but some cases of head injury are found to require a great deal, and it has the disadvantage of raising the cerebrospinal fluid pressure and of increasing the possibility of post-operative bronchitis or bronchopneumonia.

Illustrative Cases

The following examples serve to illustrate some of the principles of treatment which have been considered:

Case 1.—A saw-mill hand, aged 34, was in a stooping position in the pit below a circular saw and in the act of securing a spanner which had fallen into the pit. As he raised his head the saw began to revolve, ploughing through the scalp and skull in a sagittal direction. The engine was stopped at once, and he was taken from the pit unconscious and bleeding profusely from the wound. He soon regained consciousness and was attended by a doctor, who inserted a series of horsehair sutures to arrest the bleeding and sent him to hospital. By the time he arrived he was able to walk unassisted. Examination revealed a lacerated wound, six inches in length, just to the right of, and parallel to, the superior longitudinal sinus. Under nitrous-oxide-oxygen anaesthesia (7 hours 45 minutes after the accident) the scalp was shaved, the horsehair sutures removed, and the wound freely opened up. Both tables of the skull had been divided. Bone was taken away, and it was found that both dura and brain had also been damaged. The lacerated edges of the dura were excised and some bruised cortex was removed. The wound was closed and drained by three small Kocher's glass drainage tubes. Convalescence was uninterrupted, and the wound healed by first intention.

Case 2.—A horsewoman aged 19 was thrown on to the occiput and sustained a contused wound which penetrated the subaponeurotic space. She was put to bed and was attended by her doctor. Five days after the accident the wound edges were inflamed, the scalp and upper part of the face oedematous, and the skin of the frontal region reddened. There were some enlarged tender glands near the apices of both posterior triangles. She was admitted to hospital as an emergency case, and lumbar puncture performed. The cerebrospinal fluid was clear and as yet uninfected. Under ether

anaesthesia the wound edges were excised and multiple drains of fluted rubber placed into the subaponeurotic space. Suppuration was free, but the oedema gradually subsided and healing took place without intracranial complications. This patient's recovery was fortunate. The wound should have been excised in the first place; surgical aid was sought only when infection had supervened.

Case 3.—A golfer aged 26 was accidentally struck on the left side of the head with the driving club of a fellow golfer. He fell unconscious and was brought to hospital, where a wound 1 cm. in length was apparent in the left temporal region. The edges of the wound were slightly swollen and there was a trickle of blood from it. By this time the patient had recovered consciousness, but was drowsy. When the wound was probed a fracture could be felt, and some flecks of brain came away when the probe was withdrawn. Under ether anaesthesia a scalp flap was reflected and a compound comminuted fracture exposed just posterior to the pterion. A piece of inner table was seen to be driven into the brain. This was removed and haemorrhage from some torn cortical vessels controlled by the application of a piece of temporal muscle. Damaged tissue was excised, and the wound closed after placing a glove drain in its posterior angle. Recovery was complete and uncomplicated.

A. STUDY OF MENTAL DEFECT

REPORT BY DR. PENROSE

At least two important and extensive researches in regard to mental deficiency have been conducted in England over the last few years. One of these, under the auspices of the Burden Trust, with Professor R. J. A. Berry and Dr. J. A. Fraser Roberts as chief investigators, has been based upon Stoke Park Colony, Bristol, and on the child population of the city of Bath. The other, under the auspices of the Darwin Trust and the Medical Research Council, has been based upon the Royal Eastern Counties Institution at Colchester, and, with the encouragement and help of Dr. J. Douglas Turner, the medical superintendent, has been conducted by Dr. L. S. Penrose, in charge of the research department of that institution. Each of these researches has been productive of valuable interim or incidental publications dealing with certain aspects of the work, and their final reports have been anticipated with much interest. That of the Burden Trust has not yet been issued, though an interim note on the work appeared last autumn.¹ The Medical Research Council has now published "A Clinical and Genetic Study of 1,280 Cases of Mental Defect,"² by Dr. Penrose. It is a report of great value.

The investigation which the report describes was both extensive and prolonged. The scheme of research was planned as long ago as 1930 with the object of increasing knowledge on the causation of mental defect. About the same time the Council of the British Medical Association set up a special Committee on Mental Deficiency, which issued an informative report in 1932. In an appendix to Dr. Penrose's report reference is made to more than fifty publications on the subject during the past eight years, in addition to twenty-nine coming from his own research department: and this list is by no means exhaustive even

¹ *British Medical Journal*, November 13, 1937, p. 973.

height on to the feet, causing fracture of the base. The fractures occur at or near to the site of maximum impact, and, while it is not intended to discuss in detail the mechanism of production of fractures, some reference may be made to the term "contrecoup," which every student seems to remember. It is about as unreasonable to assume that a blow delivered to one part of the skull will fracture the diametrically opposite part as it is to expect that when we tap one end of an egg with a spoon the other end will crack. It is important to remember, however, that gross damage to the brain may occur by contrecoup, and I have several times noted extensive cerebral contusion at a point on the surface of the brain diametrically opposite the point on the skull at which the blow had been delivered and at which fracture may have taken place.

Skull fractures may conveniently be grouped into those of the base and those of the vault, since there are certain characteristics and indications for treatment that apply to each group. Many fractures, however, involve both vault and base—for example, those running through the squamous temporal bone into the floor of the middle fossa.

Fractures of the Base

The importance of fractures of the base lies in the fact that these are usually the outcome of a degree of violence which has produced much damage to the brain. Sir Astley Cooper held that fractures of the base were invariably fatal, but we now know that many cases recover. These fractures are often compound either into the nose or into the tympanic cavity, and owing to the close attachment of the dura mater over the skull base this membrane is lacerated and with it the arachnoid, so that occasionally blood and cerebrospinal fluid escape from the nose or the external auditory meatus. The clinical picture is usually that of the accompanying contusion and laceration of the brain, and treatment (which will be detailed next week in a paper on concussion and compression) must be directed to such. Owing to anatomical considerations local treatment for the majority of these compound fractures cannot be complete. Our object again, however, must be to protect the patient from infection, so far as possible, by keeping the nasal cavities or the external auditory meatus clean with pledgets of wool well wrung out of dilute phenol solution (1 in 200) and by administering 10 grains of hexamine by the mouth three times a day. This substance enters the cerebrospinal fluid, and in the presence of acid-forming organisms is decomposed, yielding formaldehyde, which is inimical to them.

Fractures of the Vault

These fractures may be simple or compound, linear or comminuted; they may be complicated either by being depressed or through fragments being driven into the meninges or the brain itself.

Compound Fractures of the Vault

Like compound fractures elsewhere in the body, these require urgent treatment with the object of preventing or at least minimizing the ravages of infection. They should therefore be operated upon as soon as possible and a surgical toilet of the wound effected. This involves the excision of damaged tissue and the exploration of the fracture, for which purpose the bone must be opened at the fracture site, if necessary by using a perforator and burr or a small trephine. If the dura is undamaged and clean, removal of bone need not proceed beyond this, but

if debris and foreign bodies are found within the skull and if dura and brain have been torn and contused a wider removal of bone is necessary, with further excision of damaged tissue. Hot saline should be used throughout, and bleeding vessels underlaid with fine catgut passed on a small curved needle or secured with silver clips. Drainage of the wound by small rubber or glass tubes is then instituted and the scalp wound closed with interrupted silkworm-gut sutures. As a rule the drains may be removed at the end of forty-eight hours and the scalp sutures on the eighth day.

It is important to open up and explore the fracture, because otherwise it cannot be ascertained how much, if any, damage has been done to the brain and its meninges at the site of fracture. Sometimes a surprising amount of road dirt is found within the skull, lying beneath the crack in the bone. This dirt has been left in the skull, which has burst open on striking the road and, as it closed, retained some of the material with which it has been in contact. Fragments of bone are sometimes deeply driven into the brain, and these require carefully removing with sequester forceps. A suction apparatus is useful in assisting the removal of intracerebral foreign bodies. In all cases of compound fractures of the vault and in grossly contaminated scalp wounds 1,000 international units of antitetanus serum should be given intramuscularly, whatever the age of the patient.

Gunshot Wounds

The principles underlying the treatment of gunshot wounds of the scalp and skull are similar to those which we have considered in the case of the more common lesions produced by street accidents and blows. Treatment for gunshot injuries is along lines similar to those already discussed. The removal of a bullet, a piece of shrapnel, or a number of shot may be difficult if the foreign body is deeply placed and not at first readily accessible, and rather than inflict undue damage on cerebral structures it may on rare occasions be advisable to leave it in place.

Depressed Fractures

All depressed fractures should be elevated, but if these are simple fractures there is rarely any indication for urgency; time may therefore be chosen when the patient's condition permits intervention. The area of depression is exposed by an appropriate scalp incision and the fragments levered into place: this may require a small opening in the bone, and the dura should be inspected for evidence of damage. Some textbooks state that certain depressed fractures may be left unraised; but in order to safeguard the patient from possibly unpleasant results that may follow it is inadvisable to leave his intracranial space diminished through encroachment by the depressed fragments, and the restoration of the contour of the skull is desirable. The wound made for the purpose of elevating the fragments when the fracture is a simple one should be closed in layers, using fine interrupted silk sutures for the epicranial aponeurosis and waxed thread or fine silkworm-gut for the skin.

Haematoma of the Scalp

A haematoma forms readily in the scalp but rarely requires any active treatment, the effused blood absorbing in the course of time; but because the central soft fluid part of the haematoma when palpated gives to the examining finger a sense of subsidence here, a depressed fracture is sometimes diagnosed. As a rule when there is any doubt a depressed fracture is not present.

psychosis was found in the families of patients with consanguineous parents: it is conceivable that the carriers of recessive defects tend to develop psychosis more frequently than other people."

Parental Intelligence and Size of Sibship

As to maternal age and the closely associated topic of birth order, their importance in relation to mongolism is naturally brought out, and they are discussed with regard to other conditions. In the investigation of sex differences no reliable evidence of sex-linked inheritance was found. The relation of parental intelligence to the size of sibship is a matter of great interest and importance, and it was studied both in the patient's own generation and also in the preceding generation.

"It appeared that in both generations the most fertile parental pairs were those whose average mental ability was subnormal—that is to say, dull parents had the largest families. Mentally defective parents and grandparents had fewer children than dull parents, but the lowest fertility seemed to be among parents of superior grade. This tendency of the less intelligent parents to have more children was partly counteracted by the high infant mortality in these families. The children of those parents in whom psychopathic tendency took the form of alcoholism were exceptionally numerous. Incidentally, alcoholic parents were very frequently dull, but their children were no more likely to be defective than children of non-alcoholic parents of similar grade, and idiots were rarer among their offspring than in the average sibship ascertained."

Some General Conclusions

General conclusions are set out not only in the final section of Dr. Penrose's report but also in the preface of the Medical Research Council and in the author's own introductory chapter. Some of them may be thus quoted:

"It is clear that there is no cleft between normal-mindedness and feeble-mindedness. Intelligence, like stature, is graded, and the distribution of intelligence throughout the community is continuous. Any study of mental defect must accordingly take into account the gradations of mental ability which are formed both among the patients themselves and among their relatives."

"Familial incidence of defect is specific to the grade of the patient. . . . There is a tendency for the intelligence of the children to resemble the mean grade of the parents."

"The highest fertility is associated with a parental intelligence which is on the borderline of mental defect as it is generally understood: as the mental grade of parent diminishes below this point fertility also diminishes."

"Some evidence has been brought forward in this survey that some severe cases of defect which appear to have recessive determination are due to genes which underlie milder conditions in heterozygous relatives."

"The probable existence of environmental causes of mental defect has been demonstrated in cases of mongolism, congenital syphilis, trauma, and encephalitis. Such causes as raised maternal age, trauma, and infection, which are easily recognized in outstanding cases, may function in a milder degree in other cases. In patients with particular diseases (mongolism, acrocephaly, congenital syphilis) there was evidence both of environmental and genetic aetiology of mental defect. Moreover, in borderline cases physical or mental diseases—for example, encephalitis lethargica, epilepsy—may easily convert an intellect which was potentially within normal limits to a level which corresponds to certifiable defect. It has never seemed at all probable that a single cause could account for all mental deficiency in the same way that the *Spirochaeta pallida* accounts for all syphilis. The aetiology of mental defect is multiple, and a facile classification of patients in the series into primary or secondary, endogenous or exogenous, cases would have only led to a fictitious simplification of the real problems inherent in the data."

MEDICAL RESEARCH COUNCIL

REPORT FOR 1936-7

The first part of this notice of the annual report of the Medical Research Council for the year 1936-7¹ was published last week at p. 625.

Hormones

The chemistry and interrelationships of the various hormones produced in the body by the endocrine or "ductless" glands are being actively investigated by a number of research workers, and references to this subject are scattered over many parts of the report. There has been an increasing tendency in recent years to regard the anterior lobe of the pituitary gland as the control centre of the whole endocrine system, and the fact that its removal causes atrophy of gonads, adrenals, and thyroid gland, with resulting secondary changes in the accessory reproductive organs and in blood chemistry, metabolism, and growth, gives support to this view. The Hormones Committee of the Council, presided over by Sir Henry Dale, has instituted a large-scale inquiry into the hormone content of the blood and urine of the human subject in health and disease. The scheme falls into four parts: (1) the investigation of methods for preparing active concentrations of the hormones from body fluids; (2) chemical and biological measurements of the active substances; (3) study of the variations in the amounts present in the blood and urine of normal subjects; and (4) assessment of the clinical significance of variations clearly beyond the normal limits.

Many features of the endocrine system have been investigated during the past year by workers with grants from the Council. The problem of the combined androgenic and gynaecogenic properties of "male" and "female" hormones has been extensively studied at the Lister Institute, and from this work it is concluded that, with the exception of progesterone, all the known sex hormones, as well as their most active derivatives, stimulate the development of the reproductive organs of both sexes, although in most cases they act on the male and female organs in different degrees. A new classification of the sex hormones has been suggested on this basis.

In the Council's own laboratories at the National Institute some attention has been paid to a study of the specificity of anti-gonadotropic sera. It has been found that an antiserum to the gonadotropic substances from human pregnancy urine will completely inhibit the gonadotropic activity, in young rats, of extracts from the human anterior pituitary lobe. As there is no difficulty in preparing and purifying an anti-gonadotropic serum of this nature, it is believed that it may find clinical applications. One unexpected finding in the work done on the hormone content of human materials is the excretion by ovariectomized women of male hormone in amounts not recognizably below the normal. Some cases of female hirsutism and virilism have shown a high level of androgen excretion, probably attributable to the suprarenal cortex. Some work has been done on pineal tissue, a large amount of which has been obtained with the aid of a sum of money made available to the Council from a private source. Detailed examination of this has so far failed to demonstrate any hormone activity on mammals. At Oxford University some further work has been done on the physiology of the menstrual cycle and on the endocrinology of the prostate gland. It has been shown that the menstrual cycle is associated with rhythmic changes, not only in water metabolism and in the concentration of the blood but also in the sensitivity of the uterus to oestrogenic agents.

Vitamin Research

No very outstanding advance has taken place in vitamin research during the year, but the subject has been pursued

¹ Report of Medical Research Council for the Year 1936-7. Cmd. 5671. H.M. Stationery Office. Price 3s. net.

of those which may be regarded as having scientific value. Yet throughout this period of time, even in some circles which would claim to be scientific—to say nothing of a wider public more or less interested in social questions—there has been but little diminution of that uninformed and facile thought, talk, and writing which was so prevalent at its beginning. Even to-day there is a demand for drastic action with regard to mentally defective persons based upon contentions which successive investigations are showing to be false, and upon naïve explanations of facts which research shows to be far from simple. The wisdom of waiting for more definite and certain knowledge is not the least important of the lessons to be derived from the special report now under review.

Plan and Scope of the Research

It has to be realized that so extensive a piece of research as that described by Dr. Penrose suffers from certain limitations. All the cases inquired into were institutional; there was no corresponding control investigation into a similar number of cases of normal persons, or even of persons of dull or defective intelligence living in the general community; data compiled from families selected because of the presence of abnormal offspring exaggerate certain results. Dr. Penrose, of course, recognizes this, and indeed is throughout very careful in stating his facts and conclusions and in drawing attention to circumstances that may affect their validity.

The report, after some preliminary observations, first sets out a description of the material investigated, and points out that although the 1,280 patients in the series were all certified mentally defective they did not form a homogeneous group. They came to the institution from various sources, and differed in sex, in age, in grade of defect, in social status, and as to home conditions. All these factors are given due consideration throughout. The three principal chapters of the report deal with the methods and results of investigation of family history, with a clinical analysis of the cases, and with the analysis of certain specific factors—familial incidence, parental consanguinity, maternal age and birth order, twins, and some others. The main text of the report occupies sixty-three pages, including no fewer than fifty-two statistical tables.

Investigation of Family Histories

The family of every case was visited on the average two or three times by members of the research staff. Facts were ascertained about the parents, sibs, and the patient's own children, and, wherever possible, about the more distant relatives. Miscarriages and stillbirths in the sibships were noted. Moreover, an attempt was made to assess the mental capacity of each relative. Obviously the sources of error in such assessment are great, and numerical results can be taken as approximate only; but the great care manifested, the detailed methods adopted, and the large number of individuals examined are alike noteworthy, and may certainly be regarded as having reduced the unavoidable margin of error to a minimum. The parents numbered 2,560; 7.6 per cent. of the parents were mentally defective, and the grade of the mothers was lower than that of the fathers. The number of grandparents was 5,114, but the mentality of one-quarter of these was not known. Of those whose mentality could be rated 0.7 per cent. were judged to be mentally defective and some 2 per cent. dull. These percentages do not differ from those to be expected in the general population.

The number of more distant relatives who were investigated appears to have been of the order of 20,000, and the results as regards those in whose cases a mental assessment could be made tend to confirm conclusions derived from the study of the more nearly related group. The commentary made in the report is as follows:

"The family history investigation has so far demonstrated certain results. The incidence of defect among parents and sibs of patients has been estimated to be of the order of 7 to 9 per cent. The incidence in patients' own children is much higher than this, but the incidence of defect among more distant relatives is considerably less. The results apply equally to both sexes for most groups of relatives, but a great many more defective mothers than fathers were found. Since no significant difference in this respect was observed for parents of male and female patients, and since defective grandparents showed little sex difference, the excess of defective mothers probably does not represent a genetic phenomenon but is largely due to a peculiarity in the selection of cases. . . . When patients were separated into groups of comparable mental grade defect was seen to be more common among relatives of mild cases than of idiots. Further, a correspondence was demonstrated between the grade of defect in the patient and the grade of defect discovered in the family: idiots, for example, though less likely to have defective relatives than simpletons, were more likely to have relatives who were idiots. Superior ability was twice as frequent among relatives of idiots as among relatives of other patients, and idiocy three times as frequent. The absolute incidence of defect varied directly with the degree of relationship."

Clinical Analysis

The clinical analysis of the cases is discussed under the headings of mongolism (63 cases), endocrine dystrophies (88 cases), congenital syphilis (50 cases), neurological abnormality (128 cases), skeletal abnormalities (142 cases), miscellaneous physical abnormalities, including deaf-mutism and eye affections (87 cases), epilepsy (210 cases), psychopathy (204 cases), and an important residual group. Neurological cases include cerebral inflammation (21 cases), cerebral trauma (23 cases), pre-natal diplegia (66 cases), and hemiplegia (11 cases). The residual group consisted of 308 patients. Their families differed in some important respects from the families of other types. The occupational status of the fathers and the home conditions were much below the general average of all types except congenital syphilis. Parents of normal mental grade were much fewer, and the proportion of defective and dull sibs was much higher. The facts suggest that hereditary causative factors have a greater degree of dominance in this group than in the clinical groups.

In regard to the analysis of special factors some important observations are made. As to specific familial incidence we are reminded that concentration of disease in a family can be produced by adverse environmental factors common to members of the family group as well as by hereditary influences. There were forty-five cases of parental consanguinity. The offspring of these showed a large proportion of idiots, of patients with cranial abnormalities, and of epileptics and diplegic patients.

"Analysis of the mental grades of parents and sibs demonstrated that consanguineous parents were very frequently dull: sibs also showed this peculiarity, and, in addition to this, idiot sibs were unusually common. There were more miscarriages and deaths in infancy among the sibs where parents were consanguineous than among the sibs of the average patient. These observations suggest that a number of cases of idiocy are due to rare recessive genes but that these genes are not perfectly recessive: in some families the heterozygotes, or carriers, are mentally dull. A rather high incidence of

system of nerves and its reactions were embodied in his Hume Lectures, published in the *British Medical Journal* early in 1937.

Research on the action of ultra-short high-frequency waves has been continued at the London Hospital and elsewhere. The work has been concerned with the high-frequency conductivity of different tissues in relation to selective heating. Grantees have also been working on the biological action of x rays and gamma rays, and the work has brought out the extraordinary variation which living cells display as regards susceptibility to radiation.

At the British Postgraduate Medical School one worker, with the aid of a grant towards expenses, has been investigating the causes and treatment of haemorrhage, with special reference to haemophilia and purpura. His conclusion is that contraction of the injured capillary blood vessels is probably the first stage in the physiological arrest of bleeding. During this stage firm coagulation of the escaped blood can take place, and the clot so produced prevents further haemorrhage when the vessels subsequently dilate. The haemostatic action of Russell's viper venom has been found by other workers to be greatly accelerated by adding small quantities of tissue extract or lecithin.

From the Bernhard Baron Institute at the London Hospital is reported a study of the ultimate distribution in brain tissue of injected thorium dioxide (thorotrast), frequently used as a diagnostic agent for mapping out the cerebral arteries. It is commonly believed to be harmless, but clinical and histological findings indicate that even the small volumes ordinarily given may cause distressing symptoms from blockage of capillaries and small veins in the neighbourhood of the compressing tumour, abscess, or haemorrhage. Another neurological investigation concerns the pathological changes in the nervous system in so-called haemorrhagic encephalitis, a rare sequel to arsenamine medication for syphilis. These were found to include widespread areas of necrosis as well as of haemorrhage around the minute blood vessels of the brain.

Finally, almost as light relief, a reference may be made to the statistical work of the Council, which is directed by a committee serving also the Ministry of Health in this special field. An analysis of the sickness experience of London transport workers was completed and published during the year, and other inquiries have been into the changes in the birth rate during the last half century and into the death rate in certain urban areas. There is indeed scarcely anything of interest to medicine or to medical sociology which the Council leaves untouched.

HEALTH OF TASMANIA

The report for 1936 of the Director of Public Health, Tasmania, states that an increasing number of local health inspectors are qualifying for the certificate of the Royal Sanitary Institute. It is hoped that ultimately none but qualified officers will be employed by local bodies. With regard to infectious diseases the report records 573 cases of diphtheria with twenty deaths during the year. Immunization was practised in only a few municipal districts. There were 478 cases of scarlet fever, compared with 302 in 1935. The cases were generally of a mild type, and there were only six deaths. Acute anterior poliomyelitis was absent during the year under review. Two nurses were sent to Brisbane to study Sister Kenny's method of treatment of paralysis. It is stated that these nurses will subsequently be attached to a public hospital for two years, where it is proposed to establish a special clinic for the treatment of infantile paralysis. A most gratifying increase is recorded in the activities of the Bush Nursing Centres, which are of special importance in districts remote from medical aid; 9,083 patients visited the bush nurses during the year, compared with 5,735 in 1935; nurses paid 8,866 visits to patients, compared with 7,634 in 1935. Unfortunately there is great difficulty in securing enough suitable applicants for posts under the Bush Nursing scheme.

THE PLACE OF THE HEALTH RESORT IN SURGERY

CONFERENCE AT HASTINGS

Another successful conference organized by the British Health Resorts Association took place at Hastings during the last week-end. It was attended by a select company of medical men from London and elsewhere and by others interested in the development of health resorts. Hastings fully maintained its reputation for hospitality, and the Mayor (Councillor E. M. Ford), who met the guests on the evening of their arrival and presided over the first session of the conference, mentioned that Hastings was among the first and had remained one of the most constant friends of the association. This was the association's second visit to the town; its first was in 1932, soon after the movement was started. The clear sky and warm sun made it possible to hold one of the principal sessions of the conference—for the discussion of the place of the health resort in surgery, pre-operative and post-operative—entirely in the open—a tribute to the English climate, and that of the south coast in particular, that such a thing should be possible in mid-March.

The discussion on the place of the health resort in surgery was presided over by Dr. NORMAN GRELLIER, chairman of the Hastings Division of the British Medical Association. It was opened by Mr. W. McADAM ECCLES, consulting surgeon to St. Bartholomew's Hospital, who emphasized in particular the value of the health resort in pre-operative treatment. The public well understood convalescence after operation, but it was as yet hardly aware of the desirable "building up" beforehand, which could be carried out most successfully at the seaside or at a spa. He suggested that some rich benefactor might establish—why not at Hastings?—a preparation home wherein during a year some hundreds of people from London or elsewhere for whom an operation was in prospect might be made fitter, under skilled medical observation, to undergo their ordeal. Mr. Eccles also urged that surgeons, before their patients went to a health resort to recuperate after an operation, should write out their "marching orders," stating exactly what they should and should not do in the way of exercise, bathing, and games. This was a great help to the patient himself, to any doctor or nurse under whose care he might be at the health resort, and, by no means least, to relatives and friends, who sometimes had the most fantastic ideas as to what was right or wrong in these circumstances.

In discussing graduated exercises for the patient recovering from an operation Mr. Eccles recommended putting the golf ball. All health resorts, he said, should have well-laid-out putting greens, surrounded by cheerful flower beds. Croquet also was an excellent pastime for those recovering tone after operation. Bowls was a little further advanced in the scale of graduated exercise. If the patient was having his convalescence in really warm weather seawater bathing was not contraindicated, provided that the length of stay in the water was not too long and the reaction afterwards was good.

Building up a Patient's Reserves

Mr. ZACHARY COPE, surgeon to St. Mary's Hospital, who continued the discussion, also stressed the value of a period of rest at a health resort before operation. The patient who had to undergo a gastric or renal operation, for example, had already gone through a long period of ill-health. Nearly all the viscera had large reserves of function which could be drawn upon in an emergency, but the patient for whom an operation was in prospect had lost his reserve. A stay at a health resort might avail to build up that reserve and so carry him through the emergency. Change of air, bodily rest, freedom from business, and careful dieting were all of special value in this connexion. He spoke particularly of the operation,

in many laboratories. Some work has been done at the Lister Institute on the enhancement of the antiscorbutic potency of canned vegetables and fruits containing vitamin C and the conferment of this activity on products not originally potent by adding synthetic ascorbic acid before processing. Apples have been tested twenty-one months after canning and no perceptible loss in antiscorbutic activity during storage at ordinary temperature was recorded. Attempts are being made to increase the potency of canned peeled apples by adding to them extracts of the peel of the fruit, which contains very much more vitamin C than the remaining portion.

Some other work carried out at the Dunn Nutritional Laboratory, Cambridge, on vitamin C reserves in infective diseases supports the view that infective diseases bring about an increased use of vitamins and a corresponding depletion of the body reserves. The influence of vitamin B₁ on gastric secretion in pregnancy has been studied at the Royal Free Hospital, but the work suggests that the acid content of the stomach varies with the season of the year rather than with the duration of the pregnancy.

An inquiry has been made into the richness of wheat and bread in the various factors which used collectively to be known as vitamin B. The work, done at the Lister Institute, has shown wholemeal flour and bread to be much richer in all the factors than the white flour and bread examined, though the latter were richer in vitamin B₁ than had been expected. All the flours and breads were deficient in lactoflavin, but the wholemeal was superior in this respect to the white. At University College, London, researches have been made into the chemical nature of vitamin E, which is thought to have a constitution similar to some of the polycyclic structures found in the sex hormones and sterols. Attempts have been made to determine the fate of vitamin A when it disappears under certain conditions from the liver, where it is normally stored. There are signs that it may be excreted in urine as a breakdown product with glycuronic acid.

Mental Defect and Disease

The relatively small amount of research in this field supported by the Council is due to the comparative lack of appeal which this difficult branch of research makes to investigators. There are so many environmental and hereditary factors at work, each demanding isolation and close consideration. An inquiry into the causation of mental defect has been undertaken, in co-operation with the Darwin Trust, at the Royal Eastern Counties Institution, Colchester. Defect has been found to be more common among parents and other relatives of simpletons than among those of idiots, although the mental defect occurring in the families of idiots is more likely to be idiocy than that of the simpleton grade. The relation of parental intelligence to the number of offspring has been examined, and it appears that the most fertile parental pairs are those whose average mental ability is subnormal; the effect of this is partly counteracted, however, by the high infant mortality in these families. Mentally defective parents in this investigation were shown to have fewer children than merely dull parents, but the lowest fertility was among the parents of superior grade. Alcoholic parents were very frequently dull, but their children were found no more likely to be defective than children of non-alcoholic parents of similar mental grade.

At Maudsley Hospital a large-scale inquiry has taken place into the incidence of different types of mental disorder among twins. An account of the findings is being prepared for publication. The Council is also collecting records from a number of London and provincial hospitals for a statistical inquiry into the incidence of consanguineous parentage among patients suffering from different conditions (not necessarily mental, of course). Owing to the infrequency of consanguineous marriages very large total numbers are required to show whether particular diseases have a high incidence among the offspring.

Tropical Diseases

A further account is given of a prolonged investigation at the National Institute upon the group of micro-organisms classified as vibrios, which include the "comma" bacillus, postulated as the causal organism of Asiatic cholera. Exact knowledge has been wanting, however, as to the possible existence of other vibrios able to produce cholera. A step has been taken towards the improvement of the diagnostic agglutination test for the "comma" bacillus. The validity of the conclusions reached in English laboratories is being tested by extensive investigation in the field, with the use of reasonably uniform reagents, and there is now hope of an early solution of important outstanding problems in the bacteriology of cholera and in the diagnosis of infection due to it, including the recognition of carriers.

A reference is made to the experimental study of leprosy. Some work has been done at the farm laboratories of the National Institute on the transmission of the bacillus of rat leprosy to Syrian hamsters, small rodents which have become objects of medical study because of their susceptibility to certain other infections. A successful attempt has been made to transmit the organism of human leprosy to these animals, and should further work confirm the early results it will provide the basis of a new attack on the problem of leprosy in man, and in particular it will make possible the experimental study of leprosy by chemotherapeutic methods.

The chemotherapy of malaria has been the special study of the unit for research on malaria at the London School of Hygiene and Tropical Medicine, working in association with the Ministry of Health centre for malaria therapy at Horton. Particular attention has been given to the inhibitory effects of quinine and other drugs upon the respiratory metabolism of isolated malaria parasite substance obtained from infected monkeys. Observations on the chemical dissociation of quinine and atabrin in the body and on the inhibitory action of anti-malarial drugs on body lipases have been published.

An attempt is being made at the Wellcome Bureau of Scientific Research to improve the method of vaccination against yellow fever, and some progress is recorded. The problem of pellagra in Egypt is under investigation by a grantee of the Council. A clinical investigation of over 200 inhabitants in villages of the Nile delta showed 34 per cent. to be suffering from this condition. The general conclusion is reached that pellagra in Egypt results from two concomitant but independent factors—namely, malabsorption due to parasitic infection of the intestines and malnutrition due to a diet insufficient in vitamin B₃ complex. Elsewhere some work is recorded which suggests that nicotinic acid may prove to be an effective preventive and curative agent in pellagra, possibly the elusive pellagra-preventing factor for which scientists have been searching for many years.

Various Work

A few other examples of work supported by the Council can be no more than mentioned. Reference is made in the report to the Lambeth cardiovascular clinic, where experimental studies of the heart have been made and the new grafting operation (cardio-omentopexy) has been carried out by Mr. Laurence O'Shaughnessy in certain cases. The comment is made that this work merits attention, perhaps not so much for its practical importance—though that is by no means negligible—but rather because it illustrates the development of a technique along systematic experimental lines and also provides a method for studying the diseased heart under normal conditions.

The report from one of the clinical research units supported by the Council—namely, that of University College Hospital—is largely occupied with the observations of the director of the unit, Sir Thomas Lewis, on cutaneous hyperalgesia and the sensory response to painful stimuli. Sir Thomas Lewis's observations on the "nocifensor"

Hastings, he continued, had been one of the first places to be visited, and had always loyally supported them. The motto of the B.H.R.A. might be "Co-operation," and this was what they had achieved with the great medical bodies. Sir Stanley then announced that the B.H.R.A. was going in the future to be entirely responsible for the publication of the official handbook. "The County Borough of Hastings" was proposed by Mr. H. L. Attwater, and Mr. M. Hely-Hutchinson, M.P., in response, reminded those present that in all cities the mortality rate was the same—namely, one per person.

On Sunday morning the party was taken by bus to visit the magnificent outdoor bathing pool, Alexandra Park, and St. Clement's Caves, while some were wise enough to take the opportunity of sun-bathing in what is said to be the highest outdoor temperature for this time of the year for ninety years.

MEDICAL LECTURES ON FITNESS

At the request of the Board of Education the British Medical Association has arranged a series of lectures, designed to bring out the medical aspects of fitness measures, which will form an important part of the special programme planned by the Board in co-operation with the National Fitness Council for the Ideal Home Exhibition at Olympia, London, from April 5 to 30. The lectures will be given daily in the fitness section of the Exhibition at 3.15 p.m., with the exception of the Easter holiday period. The following are the lectures which have been arranged:

Date	Subject	Lecturer
April 5	Opening Lecture: Why Education of the Body is Necessary	Introductory remarks by the Chairman, Viscount Dawson of Penn, followed by Capt. S. J. Parker, of the Board of Education
" 6	Nutrition, Food, and Fitness	Major-General Sir Robert McCarrison
" 7	Common-Sense Cooking	Dr. E. H. T. Nash
" 8	The Doctor and National Fitness	Sir Henry Brackenbury
" 9	Safe Motherhood	Dame Louise Mellroy
" 11	Building Healthy Children	Dr. C. K. J. Hamilton
" 12	Fitness and the National Educational System	Dr. E. J. Boome
" 13	Physical Education at Public Schools	Sir Kaye Le Fleming
" 14	The Use and Abuse of Athletics	Dr. Adolphe Abrahams
" 19	Fitness and the Industrial Worker	Dr. L. P. Lockhart
" 20	Fitness and Eugenics	Sir Farquhar Buzzard
" 21	Mental Fitness	Dr. J. R. Rees
" 22	Fitness to Prevent Tuberculosis	Dr. J. H. Harley Williams
" 23	The Dangers of Slimming	Sir Edmund Spriggs
" 25	Sunlight and Seabathing	Sir Henry Gauvain
" 26	The Treasure of Your Eyes	Dr. H. Campbell Orr
" 27	The Prevention of Infection	Dr. Andrew Topping
" 28	Health and Your Local Authority	Dr. W. G. Willoughby
" 29	The Family Doctor and Fitness	Dr. Alfred Cox
" 30	"Summing Up"	Sir Charles Wilson

Dr. Victor E. Levine, professor of biological chemistry and nutrition at the Creighton University School of Medicine, has constructed a laboratory at Point Barrow which is equipped with all the latest apparatus for carrying on medical and biological research in the Arctic.

Reports of Societies

URÆMIA

At a meeting of the Medical Society of London on March 14, with Mr. J. E. H. ROBERTS in the chair, a discussion took place on uraemia.

Medical Aspects

Dr. T. IZOD BENNETT defined uraemia as a physical disturbance resulting from renal failure of severe degree. He chose the words carefully because it was possible to have renal failure of rather severe degree without uraemia, and for recovery from quite severe renal failure to take place without uraemia occurring. The word "uraemia" implied a clinical condition, and they were not justified in using the term merely because renal failure had progressed to a point at which there were demonstrable chemical changes in the blood; there must be symptoms as well. On the other hand, it was equally important to recognize that uraemia could not appear without demonstrable changes in the blood chemistry, the principal change being an increase in the blood urea. He showed diagrammatically the main chemical changes present in uraemia—the great increase in blood urea, the diminution in the amount of calcium in the blood, the increase in phosphorus, and very often the considerable diminution in the alkali reserve. These chemical changes could be related very closely to the various clinical phenomena which constituted the syndrome. These consisted mainly in gastro-intestinal disturbance, very largely in the form of slight, going on to severe, vomiting, sometimes with diarrhoea; drowsiness, proceeding to the type of coma which was the terminal event; neuro-muscular excitability, sometimes proceeding to actual tetany and fits; and certain respiratory phenomena—either increased pulmonary ventilation or the hissing respiration of the classical type. The drowsiness and coma ran very closely parallel with the increase in the blood nitrogen, so that it was difficult to escape the conclusion that they were a direct effect of urea intoxication. The gastro-intestinal symptoms were almost certainly the result of a backward passage of the blood into the alimentary canal.

It was sometimes asked how it could happen that cases occurred with notably high blood urea but without the clinical manifestations of uraemia. If nitrogen retention was sufficiently slow and insidious in its increase it might reach an extreme degree before any great disturbance was produced; the same applied to alkalosis. It merely illustrated the very important physiological axiom that symptoms due to chemical changes in the blood manifested themselves in proportion to the abruptness of the change rather than to the mere degree of the change. For example, the chronic alcoholic was seldom drunk, and the drug addict often exhibited few obvious symptoms. As to the causes of uraemia, it was clear that anything which could precipitate renal failure of severe degree would tend to produce that condition. There was a multiplicity of possible causes, and apart from those which were purely medical there were such things as nervous shock, and it must be remembered that surgery, with all the brilliant results it had brought about in the prevention of uraemia in cases such as those of prostatic obstruction, had occasionally been responsible for the precipitation of uraemia owing to the reflex effects of passing instruments in the lower urinary tract.

Surgical Aspects

Mr. A. DICKSON WRIGHT said that uraemia came into the province of the surgeon in two ways: first in diagnosis, and secondly as a condition which he was sometimes called upon to treat owing to some obstruction of urinary outflow. Uraemia might be the result of long-standing urinary obstruction and produce unusual signs and

in debilitated subjects, which was done in two stages. After the first and relatively minor operation there was an immediate improvement, and an inexperienced surgeon might believe that the second stage could be proceeded with at once. Even laboratory tests might bear out that conclusion, but they never gave the true reserve of the patient. The recovery was sufficient for normal activities but not for emergency demands. If between the two stages of the operation the patient was sent away to a suitable health resort for a few weeks, or even, if possible, months, the chances of a successful issue were greatly increased.

After a serious operation it was also wise, if not absolutely necessary, for the patient to stay at a health resort. From the mental as well as the physical point of view it had a part to play in the rehabilitation of the surgical patient. There were patients so insensitive to the discomforts of operation that they did not appear psychologically to be much affected by the experience, but to the majority of people an operation was a matter for anxiety, and in addition to the physical strain there was a severe mental reaction. The patient who was mentally depressed after operation usually soon recovered, but in older people there often remained slight mental instability for some days or weeks. The fact that only in a few cases did actual alienation occur should not blind us to the mental strain undergone. To combat this nothing was better than a holiday in a health resort with complete change of surroundings.

As to the type of health resort suitable for surgical patients, much depended on the condition from which they had been suffering. Patients with tuberculous glands were often recommended the east coast, and for many conditions inland spas had advantages. But he thought that on the whole the south coast possessed all the essential and many specially appropriate features for the recuperation of the patient. The abundant sunshine, the richness in ultra-violet rays, and the gentle hills whereon the purifying effect of the south-westerly breezes could be fully experienced, combined to make the southern seaboard ideal.

How the Health Resort may Play its Part

Dr. G. R. BRUCE, Medical Officer of Health for Hastings, discussed the means at the health resort whereby patients might be helped to withstand the effects of an operation. He spoke particularly of what the health resorts could do to help in both the treatment and prophylaxis of surgical tuberculosis, and mentioned the work of Alton on Hayling Island, the Bishopstone Seaside Home of the Chailey Héritage, the Margate Sea-bathing Hospital, and, at Hastings, the Shaftesbury Home. Medical men who sent their patients to seaside resorts for convalescence would naturally desire them to be under the general medical care of colleagues whom they knew personally and in whom they had confidence. To ensure this friendly professional association it was important to have in the health resort a flourishing medical society combined with an active B.M.A. Division, where physicians and surgeons and various specialists could come in turn to talk. Practitioners in health resorts should take every opportunity of attending postgraduate courses in London or elsewhere and in other ways meeting consultants in their own territory.

Private nursing homes and convalescent homes were of some importance in relation to this subject. Since the Nursing Homes Registration Act, 1927, he had noted a progressive improvement in the private nursing homes of Hastings, and as regards convalescent homes there were in the town 700 or 800 beds in homes of many types. He suggested that the British Health Resorts Association might consider the compilation of a list of private nursing and convalescent homes, with particulars as to type, cost, and nursing facilities, in health resorts and spas. Many patients of course should be able to go to a hotel or

boarding-house, with a quiet but cheerful room, a modern bed, and a suitable diet. It would be an advantage at hotels at health resorts if the chef or his assistant had some of the training which the hospital dietitian now possessed.

Amenities of Health Resorts

Another session of the conference was devoted to the subject of horticulture at the health resort. Lieutenant-Colonel W. BYAM, chairman of the Medical Advisory Committee of the British Health Resorts Association, urged health resorts to cultivate horticultural individuality. The railway station of a health resort, as of most other places, gave a very unpleasing first impression. Why should not the railway square be made attractive, with a fountain, symbolical of healing waters, in the midst? It was important also at seaside places, for invalids especially, to have abundant stretches of green, a refuge from the prevailing glare. Mr. EDWARD WHITE, past president of the Institute of Landscape Architects, mentioned, among other things, the too prominent cemetery, sometimes on the hillside monopolizing the aspect, and without even the boundary planting which so carefully concealed the public parks from outside view. He said that if English people would only overcome their prejudice against cremation a great civic difficulty would be solved, and it would be easy to make beautiful gardens for the ashes without the depressing attributes of a cemetery.

Other points in the discussion related to the possibility of banishing railings from public gardens and giving some beauty to boundary hedges. A borough surveyor pointed out that it was easy to suggest that roads be tree-lined, and on a superficial aspect an urban road might appear to allow plenty of room for trees, but in fact the multitude of electric and telephone cables and gas and water mains under the road surface often made it impossible to root a tree.

The Amenities of Hastings

A visit was paid to a notable recent possession of Hastings, the White Rock Baths on the front, a very pleasing architectural construction and of surprising extent. The interior decoration is in terrazzo work, and the general colour scheme green, blue, and primrose. There are comfortable waiting rooms and rest rooms. The range of medical baths includes hot sea-water, seaweed baths, with nascent iodine, foam bath, peat bath, sulphur bath, and a spray room where hot and cold sea water at the proper pressure is available in the Aix, Vichy, and Scotch douches. The treatment is carried out by attendants holding the general certificate of the Chartered Society for Massage and Medical Gymnastics, with special experience in medical hydrology. It is claimed for the Turkish baths that they are among the finest in England, the bather proceeding from room to room and from temperature to temperature almost on the conveyor system, reaching finally the sea-water plunge. A large swimming-bath, 165 feet long, adjoins the medical bathing establishment; here the water is continuously filtered and circulated and the air brought to any required temperature. A visit was also paid to the new bathing pool, another example of the way in which modern Hastings has developed its natural advantages. The combination of spa facilities with south coast air and sunshine should be of benefit to many patients.

Official Banquet

On Saturday evening a large company sat down to a banquet as guests of the Mayor and Corporation of Hastings. After the Mayor, Councillor E. M. Ford, J.P., had welcomed the guests Sir Stanley Woodwork reminded those present of the short history of the British Health Resorts Association, which had started as the result of a letter written by the late Colonel Elliot to the *Times*. Since then, he said, the B.H.R.A. had been most happy under the energetic leadership of Dr. Alfred Cox.

manometer, the ophthalmoscope, and the urinometer. Little has been said about the importance of the study of the specific gravity of the urine, but this was very necessary in all cases where the question of renal failure presented itself. In early renal failure polyuria was almost invariably seen with urine of a low specific gravity. It was particularly when his surgical colleagues were called upon to operate in those cases which did not show any increase in blood urea but a free secretion, that they would get the benefit of the infusion of saline to which Mr. Dickson Wright had referred. He agreed with Dr. Jenner Hoskin that if hypertension prevailed great benefit was often afforded by venesection. In a case of impending uraemia without hypertension they would all agree that venesection was to be avoided.

ANTERIOR POLIOMYELITIS

A joint meeting of the Manchester Medical Society and the Liverpool Medical Institution was held at Manchester on March 2, with Professor W. FLETCHER SHAW in the chair. Dr. R. W. BROOKFIELD read a paper on infantile paralysis from the medical aspect.

Dr. Brookfield described the mode of infection and the spread of the virus in the nervous system, and also the symptoms of invasion of the disease. He stressed the importance of early diagnosis in the preparalytic stage if any beneficial effect was to be achieved by specific treatment. The ascending type closely resembled Landry's paralysis; in the early stages distinction was often only possible by finding the excess of cerebrospinal fluid protein without increase in cells which was characteristic of the latter condition. The encephalitic type of the disease, though producing such manifestations of cerebral involvement as stupor, delirium, or convulsions in the acute phase, did not lead to gross spastic paralysis. The lesions found at necropsy in acute cases and the results of experiments with monkeys did not support such a view, and spastic paralysis following an acute illness was almost certainly due to cerebral inflammation of a different aetiology. The need for examination of the cerebrospinal fluid in every suspected case was stressed: a normal fluid did not negative a diagnosis of poliomyelitis. Increased pressure, slightly increased protein, a moderate increase in the cells, and a leucocytosis curve were the main positive findings.

Treatment and Prophylaxis

In treatment lumbar puncture was of value, but there was still a division of opinion as to the usefulness of specific treatment with intramuscular or intrathecal convalescent serum. Many clinicians had been favourably impressed with the results of giving serum in the preparalytic stages in earlier epidemics, but the securing of adequate controls had proved difficult, and so a phase of scepticism had succeeded the initial enthusiasm. Despite some discouraging reports few would wish to neglect the only possible specific measure in such a grave disease. Prevention had been achieved by spraying the olfactory area, where the virus normally found entrance to the body, with certain astringent solutions. Zinc sulphate (1 per cent.) with 0.5 per cent. pantocain when sprayed into the nasopharynx of monkeys had produced immunity to infection by this route for as long as a month; this procedure was at present being evaluated in the human subject. It was essential that the spray should be directed to the right portion of the vault of the pharynx, and some experience and skill were necessary for success. The paper concluded with a summary of the methods employed by Elizabeth Kenny in promoting the recovery of paralysed muscles.

Mr. BRYAN MCFARLAND, in his paper on the relief of crippling due to infantile paralysis of the lower limb, considered mainly the deformities of the foot and gave the indications for resorting to operation in young children. One of the operations discussed was, he

thought, entirely new: he had devised it himself and practised it for five years in order to see if it could be safely recommended. It was designed for the relief of the calcaneus deformity in children, and combined direct correction of the deformity with blocking of dorsiflexion. He illustrated his paper by a cinematograph film.

Dr. R. W. FAIRBROTHER said that the aetiological agent in poliomyelitis was undoubtedly a filterable virus, which attacked nerve cells. There was much evidence to indicate that convalescent serum was useful if given within twenty-four to forty-eight hours of the onset, but after this time satisfactory results were unlikely. Serum therapy was therefore of little value in sporadic cases in view of the difficulty of establishing an early diagnosis. In prophylaxis active immunization had had disastrous results, and had been abandoned; the intranasal administration of zinc sulphate preparations had proved valuable in preventing the experimental disease in the monkey and had recently been tried in man; the final figures were not available, but in the recent Canadian outbreak the results were very disappointing. The administration had to be carried out by experienced workers as the olfactory hairs were exposed in the posterior part of the nasal mucosa, and unless this region was satisfactorily treated the hairs would not be protected. Mr. H. O. CLARKE and Dr. J. F. WARD also joined in the discussion.

At the same meeting Dr. R. J. MINNITT read a most interesting paper on developments in the technique of analgesia and anaesthesia.

HYDATIDIFORM MOLE

At a meeting of the Royal Academy of Medicine in Ireland on February 18, with the president, Dr. J. S. QUINN, in the chair, Dr. J. F. CUNNINGHAM (Master of the National Maternity Hospital) read a paper on the diagnosis and treatment of hydatidiform mole.

Dr. Cunningham stressed the value of the Aschheim-Zondek test and of x-ray examination. At the National Maternity Hospital during the last four years hydatidiform moles had been seen once in every 1,532 cases, but the real incidence was much less. Four methods of treatment had been recommended: rapid dilatation of the cervix and emptying of the uterus with the finger or with ovum forceps; vaginal hysterotomy; abdominal hysterectomy; and abdominal hysterotomy. The ten cases he had seen in the last four years had all been treated by a modified method of induction. In nine cases the uterus responded to the medicinal induction and expelled the mole with very little bleeding. In the case in which induction failed he performed total hysterectomy. Eight of the cases had been followed up and two were still under observation. In no case had chorion epithelioma developed; the absence of all trauma in the evacuation might have played some part in reducing the danger of metastasis. He described briefly the technique of induction. Quinine sulphate, 10 grains, was given at night, and on the following morning from 1½ to 2 oz. of castor oil. A few hours later 10 grains of quinine were given again, and followed by an enema and a hot bath. Pituitary extract in doses of 5 units was then injected at half-hourly intervals, the first dose being given at the same time as the enema; the total amount was never allowed to exceed 30 units.

Dr. T. M. HEALY then showed a specimen of a perforating mole, and Dr. EDWARD SOLOMONS a specimen from a case of chorion epithelioma, the pathology of which was described by Dr. G. DOCKERAY. A general discussion was then opened by the President and Dr. A. H. DAVIDSON (Master of the Rotunda Hospital), and continued by Dr. R. M. CORBET (Master of the Coombe Hospital), and Dr. O'DONEL BROWNE and Dr. A. W. SPAIN. At the same meeting Dr. F. W. DOYLE read some notes on a case of puerperal anaemia with pulmonary infarction.

symptoms, simulating a surgical emergency and luring the surgeon to a somewhat unnecessary and perhaps fatal operation. The principal mistake was in assuming vomiting and distension to be due to intestinal obstruction. The comatose uraemic patient provided a very difficult diagnostic problem at times. If he had localizing neurological signs, such as hemiplegia, and the optic disk showed oedema and haemorrhages, there was a great temptation to open the skull for cerebral tumour.

Medical uraemia, apart from its extreme diagnostic importance, had not very much interest for the surgeon, but occasionally operations were requested for renal decapsulation. Surgical or retention uraemia was almost a different condition, in which one looked in vain for muscular spasm, epileptiform convulsions, and retinal haemorrhages. The commonest type seen was that which followed operations on the urinary tract, and especially on the prostate. A biliary condition which surgeons encountered was in long-standing jaundice due to obstruction of the common bile duct. When this was corrected the patient very often seemed to be doing well, but ten or fourteen days later succumbed to uraemia. The treatment of acute surgical uraemia was to institute at once a continuous intravenous drip; if the chlorides were low normal saline could be used. Any simple procedure likely to overcome the obstruction should be carried out. In chronic uraemia the estimation of the blood urea and the urea concentration test would show what there was to contend with, and the simplest possible surgical procedure should be adopted to tide the patient over the crisis. It must always be borne in mind that an excess of surgery might turn a chronic into an acute uraemia. In all forms of uraemia the sheet-anchor of treatment was the continuous intravenous drip.

Renal Function and Acid-base Equilibrium

Dr. WILFRID OAKLEY said that for clinical purposes the alkali reserve might be taken as a useful guide in the consideration of disturbances of the acid-base balance. These disturbances had been simply classified by J. B. S. Haldane:

Acidosis:

Non-gaseous, due to (a) increased acid formation, (b) administration of acid-producing substances, (c) impaired urinary excretion of acid.

Gaseous, due to (a) depression of respiratory centre, (b) impairment of circulation, (c) pulmonary impairment.

Alkalosis:

Non-gaseous, due to (a) administration of alkalis, (b) loss of chlorine by vomiting.

Gaseous, due to hyperventilation.

Of these four types of disturbance they were concerned only with non-gaseous acidosis and non-gaseous alkalosis. In acidosis it was important to distinguish between cause and effect, for uraemia due to chronic renal disease was almost always associated with acidosis. He directed attention to the cases in which the kidney was structurally healthy but its efficiency was impaired as the result of a severe disturbance of the acid-base balance towards the acid side. This might be due to increased formation of acid—for example, ketone bodies in diabetes—or to the administration of acid-forming substances such as ammonium chloride and mandelic acid. It was not uncommon in severe cases of diabetic coma to find a blood urea of 100 mg. per 100 c.cm. or over, and very rarely the kidneys might be so profoundly affected that they were unable to excrete either ketone bodies or sugar. While healthy kidneys might function well in spite of severe disturbances of acid-base balance, damaged kidneys might be greatly affected by comparatively small fluctuations either to the acid or alkaline side. Intensive treatment of urinary infections by ammonium chloride and mandelic acid might produce a marked rise in blood urea.

So far as he knew, severe renal damage never produced alkalosis, and they were therefore concerned with alkalosis

only as a cause of uraemia. Hardt and Rivers were the first to publish a clinical account of uncompensated alkalosis due to excessive administration of alkalis, and in 1935 the speaker himself published an account of seven cases, two of which died in coma with blood-urea figures of 225 and 250 mg. per 100 c.cm. respectively. The dosage of alkalis need not be very great, and the daily intake in his cases expressed in grammes of sodium bicarbonate ranged between 21.5 and 54.8, with an average of 38.1. With regard to alkalosis due to chlorine-loss by vomiting, he thought it was the loss of chlorine rather than alkalosis which produced the renal failure. When speaking of acidosis he distinguished between this condition as a causative factor in uraemia and as a result of chronic renal disease. His general conclusion was that healthy kidneys functioned well within wide variations of the acid-base balance, though excessive changes in this balance might produce renal failure, especially if the change was towards the alkaline side. Damaged kidneys, however, could function only within much narrower limits, and it was most important in such cases to take the necessary steps to maintain the alkali reserve at a normal figure.

General Discussion

Mr. H. P. WINSBURY-WHITE described a case which illustrated the mechanical advantage which was available from the passage of a catheter. The surgeon's position was a very unsatisfactory one when he was called upon to operate on a patient with a blood urea of 240 mg., and if, as the result of the passing of a catheter, this figure could be brought down to about 20 mg., as in the case to which he referred, the advantage to the surgeon was obvious. There were cases where the renal function was so greatly impaired that the indwelling catheter would precipitate the patient into a state of uraemia, but his own experience was that this happened far less frequently than in cases in which the patient had a simple cystotomy not preceded by indwelling catheter drainage. Dr. GEORGE GRAHAM asked why patients with chronic uraemia so often had a severe anaemia in which iron was of no benefit.

Sir WILLIAM WILLCOX agreed with Dr. Bennett that the onset of the clinical symptoms of uraemia depended not so much on the degree of the uraemia or the level of the blood urea as on the abruptness of the change. A patient might come along with very high blood urea, perhaps 200 or 300 mg. per 100 c.cm., without any symptoms at all, and then an accident or an attack of influenza might precipitate the onset of very acute symptoms. A toxæmic renal condition which would quickly send up the blood urea to a considerable height, but in which recovery was common, was that which might arise from diphtheria, or from an acute streptococcal bronchopneumonia, or, again, from a chemical poison.

Mr. ZACHARY COPE confessed to grave doubts as to what uraemia was. It was not necessarily associated with disease of the kidneys. Perfectly normal kidneys could be found even in a patient dying from uraemia; often with a high blood urea the patient seemed comparatively well. Uraemia was a complex subject, probably comprising several different functional conditions, and he did not believe that they had got nearly to the bottom of it. Until they did so they would not know the difference between surgical and medical uraemia, and yet the two were entirely different. Dr. T. JENNER HOSKIN was rather surprised to have heard no mention of venesection as a treatment in certain cases of uraemia. In one or two cases in which uraemia was associated with severe anaemia he had had venesection done, followed by transfusion, and this he thought had proved beneficial. Dr. G. W. GOODHART said that it was a prevalent doctrine some years ago that although a high blood urea accompanied uraemia it had no causal connexion with it. It was a view he had always questioned, and he gathered that it was not now so current as formerly.

Dr. IZOD BENNETT, in reply, said that the real difficulty was that of sorting out the symptoms due to true uraemia, a chemical process, from the symptoms due to hypertension. He made a plea for the continued and constant use of the simple established aids to diagnosis—namely, the sphygmo-

by accident was 1,661; thirty-nine deaths resulted from injuries and forty-five from drowning. The deaths attributed to excessive drinking numbered seventy-seven.

INDIA

Association of Surgeons in India

It is proposed to create an All India Association of Surgeons with the following objectives: to advance the art and science of surgery in India; to bring together surgeons from all parts of India; to hold periodical meetings in different parts of India where matters of surgical interest will be discussed and social contact established; to publish a journal devoted to surgery in all its branches; and to do such other things as will conduce to the above objectives. It is hoped to hold the inaugural meeting at Bombay in the middle of April to establish the rules of the association and to elect officers. It is announced that the association is purely scientific, and will not take part in politics of any kind; it is entirely independent of any other medical association. The membership is open to those who practise surgery or any of its branches either exclusively or with other branches of medicine. Further information may be obtained from the organizing secretaries of the Association of Surgeons in India, "Binfield," Kilpauk, Madras.

King Edward VII Memorial Hospital, Bombay

The work of this institution continues to expand, and in 1936 there was intense pressure on its out-patient department and 370 beds. In his administrative report for the twelve months ended September 1, 1937, the dean, Dr. J. N. Mehta, mentions the growth in the number of motor accident cases treated in the hospital during the last three years, and expresses the hope that it will soon be made obligatory for the actual cost of treatment of these patients to be paid by the insurance companies or the motor-car owners concerned, on the lines of the provisions in other countries. He remarks that hospitals in India have a legitimate grievance in the fact that larger sums are being claimed in fines by the courts, while the hospitals treating these accident cases are not being reimbursed for the expenses they incur. The number of cases of this kind increased from 309 in 1934 treated in the casualty department to 457 in 1936, while in the same period the number of in-patient cases rose from 107 to 155. An average of 120 more patients attended the out-patient department daily in 1936 as compared with 1935, and there were often forty to eighty extra in-patients over the hospital's complement of beds, requiring the frequent provision of many emergency beds on the floors. Arrangements for enlarging the hospital at a cost of over 15 million rupees have been approved; half of this sum will be provided by the Governor's Hospital Fund. The cost of treatment of both in- and out-patients has fallen slightly during the last three years. The Seth Gordhandas Sunderdas Medical College is attached to the King Edward VII Memorial Hospital; there were 411 male and forty-three female undergraduate students in 1936-7. Various scientific researches are being conducted by the hospital and college, many under the auspices of the Indian Research Fund Association and the University of Bombay. Compulsory physical training having been adopted by the university, arrangements have been made for the regular physical exercise of first-year students under a full-time instructor. The construction of a gymkhana pavilion has been authorized. At the third M.B., B.S. examination of the University of Bombay in December, 1936, the students of this college won all the scholarships, medals, and prizes, while the one candidate who passed the M.D. examination with distinction in that year came also from the college. Postgraduate training is also being provided. The figures for the results of the examination of pupil nurses in the hospital in March, 1937, were the best in the Presidency of Bombay.

Correspondence

Measles

SIR.—It is to be hoped that at the end of the present epidemic of measles there will be forthcoming valuable evidence as to the efficacy of the various methods of preventing and modifying the disease. In the meantime it is safe to say that complete confusion reigns in the minds of parents all over the country, coupled with some resentment. They were told in their daily papers that measles contacts ought to be "given an injection." They demanded this, and school medical officers unable to obtain convalescent serum gave large numbers of children placental extract. From all accounts and some personal observation all these children in due course had measles not markedly different from that of their companions.—I am, etc.,

ARTHUR G. WINTER, M.B.Lond.

Crowborough, Sussex, March 15.

Acriflavine Emulsion

SIR.—May I correct a misapprehension on the part of Mr. W. A. Woodard, whose letter you published on March 19 (p. 648)? The paper by Mr. G. L. Keynes and myself did not say that the B.P.C. acriflavine emulsion has "too high" an oil content, nor did it suggest that any mere reduction in this content would be an improvement. It simply said that this preparation had no demonstrable antiseptic action, and advanced no reason for this except the "intimate admixture" of the active constituent "in an oily basis." That this intimate admixture is obtained with the aid of beeswax and vaseline may well have something to do with it, but all that we said was that the preparation is inert, and I should be grateful for a further opportunity of stating our reasons for this; I say "further," because I described the following simple experiment in both a medical and a pharmaceutical journal some years ago.

The intention in using such an emulsion is presumably that acriflavine shall diffuse out of it while in contact with a wound; if such diffusion does not take place when the emulsion is in contact with a watery medium the acriflavine can have no effect. This action can be tested for quite simply by pouring the emulsion into a tube of broth previously inoculated with bacteria. It floats on the broth, and thus furnishes a simple replica of the conditions produced when it is in contact with a wound. When this experiment is done with the B.P.C. emulsion so little acriflavine escapes into the underlying culture medium during subsequent incubation that the growth of the bacteria is not prevented, although a concentration of 1 part in 100,000 would be enough to achieve this. On the other hand, diffusion does take place to a sufficient extent to prevent growth under these conditions from a simple water-in-oil emulsion made by atomizing acriflavine solution into liquid paraffin. How the emulsions suggested by Mr. Woodard and by Dr. J. Walker Tomb (*Journal*, January 29, p. 256) would behave I do not know.

It will be seen that your correspondents and I are looking at this matter from different points of view. Their reasons for what they propose are either purely pharmaceutical (as presumably were those which added so incongruous an ingredient as beeswax to the B.P.C.

Local News

ENGLAND AND WALES

Postscript to Croydon

The Croydon typhoid epidemic is estimated to have cost the borough £22,261, or the equivalent of a rate of 2½d. in the pound. This sum includes the cost of the public inquiry, with the briefing of counsel, the shorthand notes and printing, and the fees of expert witnesses, also the additional accommodation for typhoid patients at Mayday Hospital and the transference of other patients from Mayday to make room in that institution. It includes also a sum of some £4,500, which is the provision the corporation is making in regard to claims. No one can tell, of course, what is going to be the result of the litigation which is threatened. Up to a recent date thirty-two writs had been served against the corporation, mostly by people who have lost relatives in the outbreak. A writ has been served by a local hotel proprietor whose son contracted the disease, and who had to close his hotel for two days by order of the medical officer of health. There was some talk of the amusement houses in the town taking action to recover their heavy losses, but it is understood that this has been abandoned. It is assumed that should impending actions go against the corporation a loan will be sanctioned, as has been done for other corporations which have found themselves plunged into financial misfortune, and so the indebtedness will be spread over a number of years.

Meanwhile the recommendations of Mr. H. L. Murphy, K.C., who conducted the inquiry, and which were underlined subsequently in a letter to the corporation from the Minister of Health, are bearing fruit. The corporation has agreed, on the recommendation of its special typhoid committee, to set up a water committee of the council, to deal exclusively with matters connected with the water supply. This is a reversion to a former practice. The medical officer of health is to be instructed to attend all meetings of the committee, so that in future there can be no complaint of lack of co-ordination between the public health and the water departments. The corporation has also agreed to a recommendation that, if the members of the local medical profession were in favour of it, medical practitioners should be co-opted on to the public health committee. On the suggestion which figured so largely in the course of the inquiry that a local medical committee should be appointed, it has been agreed that the members of the local medical profession shall be requested by the corporation to consider the suggestion that "in all large areas there should be some committee representing all local practitioners which, upon the occurrence of any outbreak, would be in constant and close touch with the medical officer of health." The object of this committee would be to furnish, pool, and distribute all available information as to symptoms and possible causes. A further proposal is that wherever possible, whether or not on any water-gathering ground, all cesspools in the borough shall be abolished. Croydon cannot be accused of not taking its lesson to heart, but the events and conclusions have more than a local application.

Town Planning for Health

The Royal Society of Medicine, at its reception on March 16, chose a rather unusual subject for discussion—namely, "Garden Cities and Town Planning." Mr. F. J. Osborn, honorary secretary of the Garden Cities and Town Planning Association, in an interesting address said that in the last few years town planners had become convinced that the grouping of enormously large numbers of people in one town had the character of a "development disease." He went on to show that the larger a

town became the more densely built upon must be its centre. In so far as the centre was used for industrial and business purposes the spread of the town imposed longer daily journeys on the inhabitants. London, in fact, was becoming a strap-hanging population. The increased density necessary in the centre of a growing city could be achieved either horizontally or vertically. The vertical extension was seen in the increased height of buildings and in the greater number of tenement houses. While the flats in the modern tenement buildings built for the working classes were often admirably designed, with the intelligent use of playing grounds for children, it did not appeal to him as a satisfactory basis for family life. The health implications of the effect of the modern city upon its inhabitants were obvious, and in this connexion Mr. Osborn referred to the amount of open green space that should be allotted to a certain quantity of population for outdoor exercise, and showed how short of the ideal were most of the big cities in this country. At the end of the lecture he illustrated his remarks with some interesting lantern slides.

General Infirmary at Leeds

The 170th annual report of the Board of Management of the General Infirmary at Leeds states that the expenditure of the hospital during the past year (£119,000) was the highest in its history. Ordinary expenditure was £9,000 more than in 1936, and exceeded ordinary income by £1,457. The rise in prices and the continued expansion of the work of the hospital precluded a balance on the right side. The number of in-patients treated in 1937 was 13,980, the number of new cases in the out-patient department again showed an increase, and during the year more than 60,500 people were treated as out-patients, the total number of attendances being just short of 390,000. The chairman, Mr. A. P. Nicholson, in presenting the report on March 3, drew special attention to the reorganization of the kitchens and laundry, the renewal of the sterilizing plant for the operating theatres, and the setting up of a dietetic department. The Lord Mayor of Leeds, who moved the adoption of the report, suggested that since the daily average number of beds occupied throughout the year by motor-car accident cases was twenty the Infirmary had the right to demand a contribution from the Road Fund.

Sheffield's Hospital Scheme

The voluntary hospitals of Sheffield are preparing to make a joint appeal for £1,000,000 with which to build a central hospital unit on a site near the university, a new maternity section at the Jessop Hospital for Women, extensions at the Sheffield Children's Hospital, and a recovery hospital on a site at Fulwood. The Sheffield Royal Infirmary, now 141 years' old, will in time become redundant, but the Royal Hospital (established in 1832) will be reorganized and used for some years to come. It is also proposed to build a new dental hospital near the university and a radium centre, where cancer research will be undertaken. Mr. Raymond Stephenson has been appointed chairman of the Appeal Fund Committee.

Coroners' Inquests in London

During 1937 the number of deaths reported to coroners in London was 9,006, of which 3,446 occurred in mental hospitals and other institutions. Inquests were held in 3,216 cases. The number of cases of suicide dealt with was 623, or forty more than in 1936. Very nearly half this number were persons over 50 years of age. Post-mortem examinations were ordered in 2,707 of the inquest cases and in 3,755 of the cases in which an inquest was judged unnecessary. A verdict of murder was returned in five cases, and of justifiable homicide in one. Three inquests were held in connexion with executions. Deaths from want of attention at birth increased from twenty-five to thirty-one. The number of people who met their deaths

may be best explained on the basis of a confusion between "remote and provimate" causes.

In dealing with Rous's work on Shope's rabbit tumour I may say at the outset that I am quite unable to appreciate the justification for the application of the term "revolutionary." We have here a case in which a particulate virus, in the fulfilment of its destiny inside the epithelial cells of the rabbit, irritates and stimulates them, causing thereby an increase of their functional activity which is followed by a multiplication of the cells themselves. At first, owing to the cell proliferation, there is formed a simple papilloma which is capable of malignant transformation when more prolonged irritation (the "remote" cause) produces a genetic mutation, which then becomes the "provimate" cause of the subsequent permanent malignant state of the cells. Under such circumstances there is no reason why the virus should not continue as a "guest-passenger" inside the malignant epithelial cell. A somewhat similar condition to that existing here occurs also in the case of coecidial infection of the epithelial cells of the bile ducts of the rabbit's liver.

As long as the condition remains in the simple papillomatous stage there is little necrosis of the epithelial cells, therefore little escape of the virus into the tissues, and hence little formation of antibodies against it. With carcinomatous change, however, there is considerable necrosis, considerable escape of the virus, and, as Rous has shown, though not in this context, the formation of antibodies against the virus. It should not be surprising if, after the process of trituration of such a tumour for the purpose of preparing an emulsion for filtration—in which process the liberated virus must come into intimate contact with the antibodies of blood and tissues—a filtrate is obtained which on inoculation is completely inactive.

This would appear to be a simple, straightforward, common-sense "verbal explanation" of what the virus accomplishes, of the manner in which it induces malignancy, and of the reason for its "absence" in the fully formed malignant lesions. Opposing theories must be considered, however, in regard to these points. With reference to the question of the part played by the virus in inducing malignancy Dr. Gye states that:

"The final proof that the virus acts causatively is more difficult, though it is fair to observe here that if we were now discussing any other subject than cancer the *prima facie* evidence that the virus is acting as the cause of the pathological condition under investigation would scarcely be questioned."

This expression of opinion may be left to others to assess as to its being a suitable basis for some of the dogmatic statements indulged in. In regard to the question of the "absence" of the virus in these tumours, one infers from Dr. Gye's argument that he believes that there is justification for supposing, if one reasons on the basis of analogy, that a virus exists also in mammalian and other tumours in which up to the present a filterable agent has not been demonstrated. Doubtless in this matter he has kept in mind the dangers he has pointed out as inherent in the process of reasoning by analogy. Rous (*Amer. J. Cancer*, 1936, 28, 233) argues along somewhat similar lines. He speculates, however, as to whether the virus may not produce malignancy in virtue of its having mutated, and, having done so, curiously enough embarks on a long indeterminate discussion, which eventually arrives nowhere, as to whether the virus can in fact cause malignancy.

In conclusion I would like to express some curiosity in reference to how such ratiocinations are of superior type to, and afford better results than, the "verbal explanations," "reasoning by analogy," and "pure speculation" which Dr. Gye alleges to be the hall mark of the somatic mutation theory, and which he condemns so heartily by giving expression to the sentiment that "it is unprofitable

to spend time in considering such explanations." One is entitled also to expect some justification of his assertions that the somatic mutation theory "offers no prospect of further advances in knowledge," has "no factual basis," and "ignores some well-established facts."—I am, etc.,

Aberdeen, March 14.

J. P. MCGOWAN.

After-effects of Modern Treatment of Carcinoma

SIR,—I am very glad to have Mr. James Phillips's assurance (*Journal*, March 19, p. 644) that his letter of March 5 (p. 538) was not meant as an attack on x-ray therapy, though two of your correspondents (p. 643), who describe damage apparently due to overdosage with x rays or with radon seeds, seem to agree with my first impression of his observations. In reply to his inquiry as to experimental work bearing on x-ray and radium treatment, the literature was extensive even in 1919, when Wetterer's third edition of his *Handbuch* devoted 166 pages, in chapter 13, to the "biological effects of roentgen rays," and in 1926, when in over 200 pages were summarized the biological and theoretical bases of roentgen and radium treatment, especially of cancer (and of tuberculous lesions), in the *Lehrbuch der Strahlentherapie*. In 1903 Albers-Schönberg showed that sterility could be produced in male guinea-pigs and rabbits by x rays without damaging the skin, the sexual power, or the general health. In 1922 Regaud published observations on the testicle and its response to x rays in animals; upon these was based the "protracted-fractional" x-ray method, found especially valuable in laryngeal cancer. Many other workers here and abroad have made valuable biological observations of use in the practical irradiation of patients; the range is from gene-mutations to total teleroentgentherapy. But if, for example, breast cancer be considered as one of the most promising fields for x-ray therapy, it must be evident that irradiation of the breasts of small laboratory animals cannot help much towards solving the problems met with in patients; the great advances in methods and results in breast cancer have been due to analysis of methods and their variations and the results of treatment in many patients over a long period of years. As in many other departments of medicine the final test is clinical, not experimental.

As regards damage, I remember in my own practice hardly any cases of serious damage, certainly not of internal injury; several skin or superficial injuries resulted from methods long abandoned. It should be generally realized that a large number of experts in radiotherapy can show in their results a considerably less proportion of cases of damage due to the treatment of malignancy than is usual after any other effective treatment. Recent advances in the measurement of dosage should render still more unlikely any serious damage to patients in the future, just as the injuries to operators can now be completely guarded against.—I am, etc.,

London, W.1, March 19.

J. H. DOUGLAS WEBSTER.

STR.—The letters of Mr. James Phillips and others indicate the existence of considerable disquietude regarding the justification of radiotherapy. Criticism in the tone of these letters serves the useful purpose of ventilating such doubts, and acts also as a stimulus, but it is only just to those who are working in this branch of medicine to state that during the last twenty-five years there has been an enormous amount of research on the effects of radiation on animal tissues, and also on the physics of radiotherapy. As this work is highly technical it has been published for obvious reasons in journals specially concerned with the

formula), or they are based on an expectation that the preparation will act in a certain way, without any proof that it does, beyond Dr. Walker Tomb's bare statement that his emulsion is "highly antiseptic." The study of antiseptic methods has made me somewhat sceptical, and I ask that assertion shall be accompanied by proof that an agent does or at least can act in the way alleged. Such proof is sometimes very difficult to devise, but here it is exceptionally easy. It should be a simple matter to estimate the amount of diffusion of acriflavine from an emulsion into water with which it is in contact, the area of contact, time, and other relevant factors being regulated and appropriate; a preparation from which diffusion produces an adequate concentration of acriflavine in the water will be an antiseptic in practice, while one which does not certainly cannot. I hope that when a change is made in the official formula it will be supported by some such study of physical properties, on which antiseptic activity must clearly depend, if not by tests of antiseptic activity itself. I suspect that in any such tests activity will be found to vary inversely with stability; in other words, that the perfect preparation from the pharmaceutical point of view will be almost useless from the surgical.—I am, etc.,

London, E.C.1, March 21.

LAWRENCE P. GARROD.

Chalk and Typhoid

SIR,—We are apt to ignore what we cannot clearly visualize. At the foot of chalk cliffs at low tide large amounts of fresh water are often found gushing up through vertical joints in the chalk. Sometimes a good example of one of the ways in which these chalk springs are fed can be seen in vertical section in low cliffs. Large funnels, apex downwards, have been dissolved out of the chalk by water seeping down, and the funnels have become filled with sandy clay and flints. At the junction of a funnel and its contents there is a layer of highly porous, half-decalcified chalk, which is a water channel in times of rain. In other words, water sinking into chalk tends to take definite channels, which must greatly accelerate its flow downwards into open joints. In the natural elimination of typhoid time is the essence of safety, but the organism can live more than a week in chalk water in the dark. Water gathered into definite channels can go a long way in a short time if there is a good supply of it, like the water from baths draining through a septic tank.

When the number of organisms in the Addington well jumped from 10 per c.cm. in the year 1902 to 3,820 per c.cm. in the year 1903, one and a half tons of sodium chloride were put two miles from the well and washed into the ground with 40,000 gallons of water. The salt began to reach the well in twenty-two and a half hours (Geological Survey Memoir, *Water Supply of Surrey*, 1912). Later a chromogenic bacillus was used with comparable results. Chalk in the neighbourhood of houses and for long distances from them is a highly dangerous formation from which to obtain untreated drinking water. We have had the Worthing, the Stroud-Rochester, the Caterham, the Newport, the Guildford, and other epidemics from chalk water. Chalk areas are becoming more and more built over. Where is the next epidemic going to be? It is time that it was clearly recognized that the water from chalk in populated areas must be chlorinated or stored before use, and that the position of camps on chalk should be properly chosen.—I am, etc.,

London, W.C.1, March 16.

C. M. HEANLEY.

Causation of Cancer

SIR,—In replying to some of the statements in Dr. W. E. Gye's article in the *Journal* of March 12 (p. 551) I do not propose to state formally a case for the view which I, amongst others, hold, that tumour formation, apart from the occurrence of teratomata, etc., is due to a mutation of genes in somatic cells. Dr. Gye seems to regard all such views as mere "verbal explanations." Actually, many firmly established facts in genetics, genies, and embryology form the basis on which the views in question are founded. One infers from Dr. Gye's remarks that something other than "verbal explanations" is the stock-in-trade of the supporters of the view of a virus being the "proximate" cause of malignant growths, in defence of which he quotes two investigations: "one by Foulds, who worked with a dibenzanthracene tumour of a fowl, and the second Peyton Rous's revolutionary work with the Shope papilloma."

With reference to the first item of this programme of justification, it may be said that the form and function of any body cell are determined in the long run by the interaction between specific genes inside the cells and their environment. If these two are normal, a normal cell is the resultant; if, however, the environment is abnormal, this leads to abnormal form and function and, in time, to a mutation of the genes, leading in turn to abnormal form and function of the cell even in a normal environment. It is legitimate to suppose that the genes produce their specific effect by means of hormones of an intimately specific nature. The employment of the term "hormone" in this context possibly requires justification. Where cells are in active process of growth, division, and development, as in the early stages of the embryo, hormones are formed in excess, escape from the cell body and cause primitive undeveloped cells to develop along the lines of the originating cell. These hormones are the "homoiogenetic hormones" of the experimental embryologist. When active growth ceases such hormones, being produced in less quantity, are used up as manufactured in the internal economy of the originating cell. We have, it would seem, an actual application of this process (not an analogy) in tumour formation in birds. The slow-growing fibromata produce no "filterable agent" (homoiogenetic hormone), while the fast-growing sarcomata form considerable quantities of this substance which, acting on the primitive undeveloped cells of the reticulo-endothelial system, cause them to develop along the lines of the originating sarcoma cell.

A tumour cell in regard to form, function, etc., is abnormal or foreign to the normal healthy bodily organism, this being due to an abnormal (mutated) series of genes being in control of its destiny. Such abnormality provokes a reaction on the part of the normal body and, because of this, antibodies of high specificity are formed against the genes themselves or their specific products. As in other immunological spheres, however, there is the production also of group antibodies. Accordingly one may regard the antibodies produced in Dr. Foulds's rabbits subsequent to injection with the Berkefeld filtrate of the dibenzanthracene tumour as being specific antibodies directed against the genes, etc., of the tumour cells but capable, owing to their group reaction powers, of neutralizing the genes, etc., of the cells of a nearly allied tumour, the Rous No. 1 sarcoma.

If this "verbal explanation" of the facts has no other merit it has at least that of attempting to explain the fact of the characteristic specificity of such tumours—a specificity, be it remarked, which represents the very crux of the whole question and which, singularly enough, has been almost totally neglected in the consideration of the subject. In saying this I am not unmindful of the fact that Dr. Gye, in his earliest pronouncements, considered that a specific factor was necessary in addition to a virus in the causation of malignancy. This early view of his

factured in this country in adequate quantities. There are a few important products in the chemotherapeutic class which are not yet made here because they are the subject of foreign-owned patents, but in the event of a national emergency, however, licences could be obtained under British patent law to enable these products to be manufactured here. My association believe that the steps taken by the Government in granting a subsidy for chemotherapeutic research will do much to assist still further in the development of this important field of work.—I am, etc.,

J. DAVIDSON PRATT,

General Manager and Secretary,

The Association of British Chemical Manufacturers.

London, W.1, March 17.

"Gonococcus Antitoxin" for Gonorrhoea

SIR,—Everyone will welcome the paper by E. T. Burke, J. Gabe, A. H. Harkness, and A. J. King in your issue of March 19 (p. 605), but, as your annotation (p. 629) states, there can "rarely have been a flatter contradiction" between the findings of the writers of the above paper and those published by myself. Contradictory results in an attempt to evaluate new forms of treatment are, of course, not unknown. It is to be hoped that the cause of the failures described will be discovered, as obviously the situation cannot be left as it is at present.

The authors of this communication appear to have had a large number of serious reactions, whereas in my own clinic, although reactions are not uncommon, they are easily controlled, and the cases continue to be treated as out-patients. Since December 2, 1937, all the male out-patients attending the venereal department of St. Thomas's Hospital, suffering from acute gonorrhoea, who can attend regularly have been receiving daily doses of 1 c.cm. of the antitoxin as routine, with adjuvant treatment. This could not be done, nor would I permit it, were they obtaining no therapeutic benefit or experiencing the severe reactions described in such a high percentage by E. T. Burke *et al.* At the moment forty-five patients in this current series are under observation and treatment. Since that date not one has necessitated admittance either for a serum reaction or for any extension of the infection as described by your contributors. The only reactions experienced in this series were two cases of urticaria and one stiff buttock. Two other patients defaulted for a reason unknown, but this proportion is not as high as the general default rate throughout the clinic. No case refused further treatment.

The cases described in the article apparently received no other treatment except the antitoxin; the authors purposely avoided giving any additional treatment in order to render the test more rigid. On the other hand, it is possible that the antitoxin acts more effectively when adequate drainage is established. In my own practice at the present time irrigations, dilatation, prostatic massage, etc., are also carried out with this end in view, although in my preliminary paper this procedure was inadvertently omitted from the text, but subsequently discussed in your columns.

Upon analysis of twenty-five consecutive cases treated in the latter part of last year the results are comparable to those already published by myself. As it is impossible to give full details of the protocols here I will gladly submit these records to the authors. They are not from my pen but are the routine observations written by my various medical colleagues in the venereal department at St. Thomas's Hospital.—I am, etc.,

London, W.1, March 21.

T. ANWYL-DAVIES.

Treatment of Acute Poliomyelitis

SIR,—We were indeed surprised to read an article in the *British Medical Journal* of January 22, 1938, written by Dr. F. H. Mills. Dr. Mills, I understand, has been a graduate for four years. During that period I can discover no evidence of his special association with the treatment of those affected with crippling diseases, when such treatment is carried out either by the orthodox method or that evolved by Sister Kenny.

In speaking of those treated by orthodox methods he states: "These cases are complicated by trophic changes and deformities which arise from muscle imbalance." Further on, in speaking of those treated by the Kenny method, "In no instance has trophic change or deformity developed." I would refer him to the report of the Royal Commission appointed by the Queensland Government after observation of cases treated by Sister Kenny extending over a period of two years.

"The Commission witnessed deformities developing in cases actually under Kenny Clinic treatment." Also: "Case of No. 51, who was splinted carefully and with particular reference to the likelihood of hip dislocation. For over four years this dislocation had been avoided and the patient was using a 'walking caliper.' Attending the Elizabeth Kenny Clinic during the surgeon's absence this patient was advised to walk without the 'caliper'—or at least permitted to do so. This resulted a few days later in a dislocation of the hip-joint, and the calcaneo-valgus deformity of the foot (which is always difficult to prevent) was found later on to be increased. In the words of the surgeon concerned, this patient 'represents the loss of a struggle for four or five years to prevent a dislocation of the limb and a calcaneo-valgus dislocation of the foot.' Again, 'The departures from orthodox treatment, especially the present important points of difference, could be, and actually were, responsible for damage beyond and in addition to that already sustained by the patient.'"

Dr. Mills condemns splinting and immobilization, yet later on in his article we read: "Foot drop and external rotation are prevented by an easily adjustable foot block." I suppose this is not splinting? Again, referring to the Commission's findings:

"For the prevention of foot drop she fits on the feet an apparatus which, in her own words, 'has to be rigid to prevent foot drop.' Also, 'Miss Kenny's views regarding the use of calipers are very confused. After roundly condemning their use on account of the evil results depicted in her textbook (page 19) she approaches the views of orthopaedic surgeons when she states that 'all possible power should be restored before calipers are used.' In spite of this dictum, however, Miss Kenny now directs that calipers be used in some of the cases actually attending the clinic for treatment. The Commission has observed that on this question, as well as in other details, Sister Kenny's treatment has undergone a gradual but distinct change towards orthodox methods."

Dr. Mills's discussion of the principles of the Sister Kenny treatment is somewhat confusing, and to me seems to be somewhat original but not convincing. Under the headings "Results of Treatment" and "Summary" I would like to ask Dr. Mills on what he is basing his opinions: on his own personal observations or on the statements made by Sister Kenny? Again, is his criticism of orthodox methods born out of ignorance or after long-continued observation of cases so treated by himself or others? We in Queensland are very surprised that such an article should be published and given such publicity. It is being widely used in the public press by Miss Kenny to condemn the orthodox methods.—I am, etc.,

HAROLD CRAWFORD, M.B., B.S.,
F.R.A.C.S.

Brisbane, March 7.

* Mr. Crawford encloses with his letter an extract from the *Medical Journal of Australia* of January 29, 1938, containing Appendix C of the report of the Queensland Royal Commission on Modern Methods for the

subject. As a result of these experiments it can be confidently stated that:

1. "The trial-and-error method of treatment" (to quote Mr. James Phillips) is unjustifiable and reprehensible.

2. The lethal cancer dose is very near the tissue tolerance dose, and the object of scientific radiotherapy is to apply the dose uniformly to every portion of the new growth; overdosage is followed by necrosis of the surrounding tissues and almost invariably great pain; underdosage by recurrence of the growth.

3. The homogeneous dosage cannot be achieved by haphazard implantation of needles or seeds. Scientific radiotherapy is not just sticking so many needles an equal distance apart into a new growth, or giving a few exposures to deep x rays.

4. Before insertion of needles the size of the tumour should as far as possible be accurately determined, and then the specific amount of radium calculated which, distributed according to certain principles (the clinical application of which has been fully described by Patterson and Parker, *Brit. J. Radiol.*, 1934, p. 592 *et seq.*), will give the lethal dose to every part of the growth but will not destroy the surrounding tissue.

5. If these methods were followed by all who elect to treat cancer by radiotherapy there would be fewer catastrophes such as those mentioned in the recent correspondence on the subject.—I am, etc.,

Sheffield, March 21.

RUPERT HALLAM,
Chairman, Executive Committee,
Sheffield Radium Centre.

SIR,—Mr. James Phillips (March 19, p. 644) asks for research to be carried out on animals on the effects of radiation on normal tissues by one of the cancer research departments. An immense amount of work of this kind has already been done and is going on in many places, but radiotherapy is not by any means in the infantile stage of development that Mr. Phillips's mention of trial-and-error methods suggests. What is lacking is an interest of the profession generally in the scientific side of radiotherapy and the therapeutic as distinct from the accidental effects of radiation. This lack of interest and the consequent lack of knowledge results in the attitude of generalizing from a few cases and condemnation on insufficient evidence which all branches of the profession have doubtless suffered from time to time, often at the hands of the lay public. Moreover, the reputation of radiotherapy is also apt to suffer as a result of its use by the amateur.

In the interests of the patients, what is needed first is free co-operation between surgeons and radiotherapists of experience so that suitable cases are selected for radiation or surgery, and cases unsuitable for treatment are rejected. Secondly, the radiotherapist, a person experienced in the clinical effects of radiation and with a knowledge enabling him to dose accurately, must treat each case on its merits. Thirdly, the rest of the profession must realize that scientific radiotherapy is not merely a possibility but a reality, although, as in other branches of medicine, precision and extension of the range of knowledge (of the reaction of both normal and malignant tissues to radiation) are rapidly increasing. Born of this realization there should develop a more tolerant attitude to the mistakes, bound to occur in every new method of treatment, but less advertised in some branches of medicine.

I should like to bring to the notice of those for whom it is necessary one or two facts concerning radiotherapy. Planning of treatment should always be as precise as is

compatible with clinical and physical considerations. When this has been done the dose to destroy the neoplasm should be uniform and sufficient to cause an inflammatory reaction of the normal tissues. In the skin this goes on to a moist desquamation or, in larger fields, to a dry desquamation, and in the mucosa to a fibrinous reaction. The reaction should heal completely, leaving normal tissue and no neoplasm. Some tumours do not respond to this tissue tolerance dose, while others respond to less. The general effects of radiation on the well-being of the patient depend chiefly on the volume of tissue irradiated and the dose it receives.

Most patients recover from the course of radiation within two or three weeks. There are individual idiosyncrasies and psychological considerations, however, which may be unknown and intractable factors for some time to come. Such considerations apply also to other forms of treatment. For those interested, some idea of the kind of work in progress could be obtained quickly from the *Year Book of Radiology*.—I am, etc.,

Sheffield Radium Centre, March 19.

FRANK ELLIS.

SIR,—The correspondence started by Mr. Percy Furnivall's account of his unfortunate experience (*Journal*, February 26, p. 450) can do nothing but good if it leads to a more careful consideration of all aspects of a particular case before the decision is made between surgery and irradiation as the prime weapon of attack. Is not the heading of this correspondence in itself propagandist and misleading in implying that the "modern" treatment of carcinoma is radiological? Radium and x rays are indeed valuable methods of treatment, in some cases by themselves and in others as adjuncts to surgery. Nevertheless, it is unfortunate when from either enthusiasm or a failure to visualize all aspects of the case surgery is displaced from its proper position in the attack on cancer. The desire of the patient to avoid in any way possible a surgical operation is sometimes responsible for bad judgment. It behoves us to be increasingly careful, now that we have more than one weapon with which to attack the disease, to choose wisely. Let us not forget that our aim is the cure of the patient, with the least possible disturbance of his future well-being.—I am, etc.,

London, W.1, March 18.

E. G. SLESINGER.

Chemotherapeutic Products

SIR,—In order to dispel any public anxiety which may arise from the comments in the Press regarding a possible drug famine in the event of war, I am instructed to submit the following observations on behalf of the members of this association engaged in the production of drugs and medicinal products.

The comments in question relate to the recently published report of the Medical Research Council, in a paragraph of which it is stated that "the special needs of the British Empire in this respect have to be met almost entirely from foreign sources." It is understood that this paragraph was intended to refer exclusively to one class of chemical compounds known as chemotherapeutic products, which are of great importance for the treatment, *inter alia*, of tropical diseases. The comments in the Press show that it is liable to grave misinterpretation, and this we wish to correct. During the last twenty years the British chemical industry, with the stimulus given by the key industry duties, has made such great strides that the position to-day is vastly different from what it was in 1914. Most of the synthetic products which are essential to the health services of the Empire are now manu-

Early Occurrence of High Blood Pressure

SIR,—Dr. E. Joan Rooke's account of a case of coarctation of the aorta (*Journal*, March 12, p. 564), with her quotation of Sir Thomas Lewis's statement in which he mentions the lack of records of these cases in the periods of childhood and adolescence, encourages me to record the following case.

The patient, aged 3 years 10 months, is the female child of an English mother and Italian father. The diagnosis of coarctation of the aorta was made seven months ago. Her history shows nothing of very much importance, except that she has always been a rather pale child. She has an enlarged heart with the apex beat palpable, but not easily visible, in the fifth left intercostal space about 1 cm. outside the mid-clavicular line. She has a systolic murmur audible in the aortic area, and rather more audible at the apex; the murmur is soft and no thrill is present. A systolic murmur is also audible along both sides of the sternum. At the back in the interscapular spaces a much louder and rather more harsh murmur is present, and this is most marked near the left scapula. There is complete absence of the femoral pulses on both sides, and it has been impossible to obtain a popliteal blood-pressure reading. In the right arm the systolic blood pressure is 136 mm. Hg. and the diastolic 85 mm. Hg. In the left arm the systolic pressure is about 10 mm. lower than in the right, but the diastolic is much more difficult to record because there is no sharp line of demarcation in the arterial sounds, which just fade away into inaudibility. It seems, however, to be in the neighbourhood of 70 mm. Hg. I assume that this difference in pressures on the two sides is accounted for by a difference in size of the anastomotic fields into which the vessels of both sides immediately empty; this is perhaps also suggested by the difference in intensity of the interscapular systolic murmurs on the two sides. When the diagnosis was made last year the systolic pressure on the right was 120 mm. Hg. and the diastolic was 85; the difficulty in recording a diastolic pressure in the left arm was also present then. Pulsation can be felt in the interscapular regions and both axillae, but throbbing anastomotic vessels are not visible; the child is well covered with fat. The radial arteries throb very markedly and are easily visible. Capillary pulsation can be demonstrated in the lips.

As in Dr. Rooke's case radiography did not show any erosion of the ribs, but this probably takes several years to develop; the aortic knob was seen to be very poorly developed, and the cardiac enlargement was confirmed. The retinal arteries are already obviously tortuous in this case, and contrast very strikingly with the appearance of the retinal vessels in normal children of the same age.—I am, etc.,

Birmingham, March 12.

HERBERT J. WILLIAMS.

Recurrent Dislocation of Shoulders

SIR,—The following case of recurrent dislocation of both shoulders would seem worthy of publication from the standpoint of symptomatology.

I was called to see a young athletic fellow, 24 years of age, a good swimmer and a fine badminton player, said to be suffering from a fit. On questioning him, his sole complaint was intense pain in both hands. He was resistive to all attempts at examination, so hyoscine hydrobromide, 1/100 grain, was given and instructions left to watch him carefully. About two hours later I received a telephone message that "his shoulders had slipped down," and on arrival I found he had a subgenoid dislocation on both sides. These were reduced by Kocher's method with the greatest of ease and without an anaesthetic. He refused to have any form of fixation, saying that this accident had occurred before and he "put the dislocation right himself." One hour later the right shoulder became dislocated

again with light massage; so he had to submit to having it fixed with plaster.

The points of interest about the case are: (1) the fact that he only complained of the referred pain caused by pressure on the plexus and possibly brachial artery; (2) the fact that he could play a vigorous game of badminton without dislocation taking place, except at rare intervals; (3) the fact that he did not complain of any impairment of movement of the limbs after both had been dislocated.—I am, etc.,

Kingston, Jamaica, Feb. 1.

C. MAXWELL JOYNER.

Chronic Littritis

SIR,—In the *Journal* of March 12 (p. 594) Dr. Sydney M. Laird disputes the part played by excessive pressure in the production of chronic littritis. In my paper (February 26, p. 448) I remarked on the tendency of concentrated solutions to cause urethral damage, but stated that apart from this the hand syringe alone could cause chronic littritis. I cannot agree with Dr. Laird that an admission of the harmfulness of concentrated solutions "cannot be reconciled with the pressure theory." The use of such solutions is commonly associated with the use of the hand syringe. I have notes of several cases in which improper solutions were not used but either the hand syringe, or an excessively elevated douche of the hydrostatic type, had been used, and chronic littritis developed. Dr. Laird speaks of "failure to promote and maintain adequate dilatation of the urethra": the normal function of the urethra is to pass fluids at low pressures, hence the use of high pressures in treatment is unphysiological. Theoretically one would expect high pressure to force material into the glands of Littré, and while the main urethra can empty itself readily and is flushed by the urine, the antiseptic solution forced into the tortuous glands is not easily removed. Thus the glandular epithelium is subjected for prolonged periods to the action of the foreign solution.

The urethroscopic picture of dilated gland mouths, though not conclusive, is suggestive of the part played by pressure. I am unable to agree as to the importance of second infections. I know of many cases of repeated infection, including cases which have been reinfectured while still under treatment, which have not shown subsequent chronic littritis. The high incidence of chronic littritis which Dr. Laird has found when treatment with sulphaniilamide and irrigations is given from the outset has certainly not occurred in my experience. Of eleven cases which he quotes, two had had gonorrhoea previously, one was first seen six weeks after the discharge began, and one had used a home irrigator—the evidence given does not exclude the possible use previously of excessive pressure. The case with phimosis is interesting. I suggest that the mechanism was that the urethra had been irrigated from within with an infected fluid (urine) at an abnormal pressure.—I am, etc.,

Plantar Warts

SIR,—I read with interest the article by Dr. R. M. B. MacKenna on plantar warts (*Journal*, March 5, p. 509). The single wart can be anaesthetized satisfactorily with a local anaesthetic if the injection is given slowly. The fibro-fatty tissue of the sole of the foot is very unyielding, and a rapid injection of fluid causes local distension and pain. The novocain takes some time to diffuse into the tissues. I have had some instruments resembling a set of cork-borers made. One is chosen slightly larger than

Treatment of Infantile Paralysis, which criticized the article by Dr. Mills in the *British Medical Journal* of August 28, 1937. The summary of the Commission's findings was reproduced in our issue of February 12, 1938 (p. 350).—ED., *B.M.J.*

Infantile Pyloric Stenosis

SIR,—Mr. David Levi (*Journal*, March 19, p. 646) admits in his reply to my letter (March 5, p. 538) that he has no "practical knowledge" of the treatment of pyloric stenosis with eumydrine, yet he describes the account of my personal experience with this line of treatment as "inaccurate." The object of my first letter was not to recommend that all cases of pyloric stenosis should be treated as out-patients, but to refute Mr. Levi's wholesale condemnation of the treatment of the condition with eumydrine, and to assert that hospitalization is not essential to a successful issue. While I cannot boast the extensive acquaintance with the disease that Mr. Levi manifestly has (never in my life have I seen twenty-eight cases in the course of thirteen weeks), I have nevertheless had the care of a sufficient number of these infants to be able to assure him that hospitalization is not necessary so long as an operation is not called for. No one, I suppose, would deny that some degree of dehydration is present in all cases with active symptoms, but it does not necessarily follow from this that saline transfusions must be administered. The question turns entirely on the degree of dehydration, and if the malady is recognized early—which I am pleased to note is occurring with increasing frequency—dehydration will be more often negligible. In any case, surely it cannot be asserted that for the administration of saline transfusions admission to a hospital or a nursing home is a *sine qua non*.

I frankly admit that my opinion of the value of radiology in the diagnosis of pyloric stenosis "is not universally accepted," but this is no proof that it may not be the right opinion. In conclusion, may I be permitted to commend to Mr. Levi the wisdom of gaining some "practical knowledge" of the value of eumydrine in the treatment of this disease as well as of the value of radiology in its diagnosis. It is the only way of acquiring a correct perspective.—I am, etc.,

London, W.1, March 19.

LEONARD FINDLAY.

Mental Disease due to Parasites

SIR,—At a recent meeting in Paris of the Advisory Health Committee of the League of Red Cross Societies the representative of the National Red Cross Society of Colombia, Professor Calderon, drew attention to the importance of the part played by parasites in mental disease. As secretary of this committee I am trying to collect information on this subject, and would be very grateful to any of your readers who would be kind enough to refer me to literature on it.—I am, etc.,

CLAUDE LILLINGSTON.

Classification of Adventitious Sounds

SIR,—As a student, some years ago, I was puzzled at times over the different classifications of adventitious sounds in the lungs as heard through the stethoscope adopted by various authors. I confine my remarks to those sounds usually described as rales and rhonchi, and extract from three books these definitions.

In *Clinical Methods* (1935), Hutchison and Hunter call all adventitious sounds rales, and subdivide them into two types:

dry (rhonchi), which may be sibilant, medium-pitched, or sonorous; and moist (crepitations), which may be (a) non-resonant and toneless, of a fine, medium, or coarse type, and (b) resonant (metallic or consonant) and of a medium or coarse type. Price (*A Textbook of the Practice of Medicine*, 1925) describes rhonchi as sibilant or sonorous; rales as "crackle, bubble, or gurgle"; and crepitations as "fine, hair-like, crackling sounds." Taylor (*Practice of Medicine*, 1922) also describes rhonchi as sibilant or sonorous; rales as "crackle, bubble, or gurgle"; and crepitations as "very fine rales."

Taylor and Price, in these editions, agree on the classification but differ from *Clinical Methods*, the authors of which consider moist rales as identical with crepitations. May I, in all humility, suggest that as a practicable working classification these adventitious sounds cannot be subdivided much further (with any benefit) than into five: (1) crackle, (2) bubble, (3) gurgle, (4) whistle, and (5) wheeze. Or, if it be preferred, into three: (1) a crepitation or a crackle, (2) a rale or bubble, and (3) a rhonchus or wheeze. Most people, I think it will be agreed, almost always confine their descriptive terminology to crepitations, rales, and rhonchi.—I am, etc.,

W. C. D. WALMSLEY.

Use and Abuse of Carbolic

SIR,—At the opening of the Bernhard Baron Laboratories Sir Charles Sherrington is reported as telling us what we might expect Lister's feelings to be if his marble bust could see and hear on that occasion. On another page of the same issue of the *Journal* (December 11, 1937) Mr. Norman C. Lake, in his article on surgical procedures in general practice, opines: "It is unlikely that he [the general practitioner] will follow Lister to the extent of using carbolic. . . ." On the other hand (both hands really), the practitioner is advised to use a 1 in 1,000 solution of biniodide of mercury in industrial spirit for sterilizing his hands. In his report on the preparation of catgut Professor Bulloch condemns in no uncertain terms this self-same spirituous solution, and adds that though most widely used in hospitals it is not as potent as a watery solution, but both are unreliable. Bulloch also demonstrated that spirit in any strength is only weakly antiseptic, yet it is used universally to sterilize syringes.

Mr. Lake recommends spirit for all syringes except those grossly infected. Where is the line to be drawn? Lister used carbolic lotion for the skin and for instruments all his life, but he used it intelligently. Because others did not use it intelligently he found it necessary quite early in the development of the antiseptic system to defend carbolic—one of the many reagents tested—against the groundless objections voiced by a multitude of heedless users. This defence is admirably set out in a clinical lecture.¹ The readiness with which carbolic lent itself to abuse caused Lister to regret his choice of it; for, after all, as he tells us, any active antiseptic will meet the case, but a solution of biniodide of mercury is not one of them. Under these trying circumstances I can only advise the general practitioner to go up to the Royal College of Surgeons in Lincoln's Inn Fields, take a good look at the marble bust of Lister, and say to himself:

"Believe not each accusing tongue
As most weak people do,
But still believe the story wrong
Which ought not to be true."

Pneumonitis

SIR,—There are many points calling for criticism in the paper on pneumonitis by Dr. A. Morton Gill in the *Journal* of March 5 (p. 504), but I am proposing to confine my attention to his remarks on tuberculosis. In the first place, he seems to accept a dilution of 1 in 1,000 tuberculin as sufficient for pronouncement on a Mantoux test, although most workers in this country perform a third test (1 in 100) before passing a final opinion: it is impossible on this criterion to credit his apparent proof that some of his cases were non-tuberculous. Dr. Gill doubts whether the allergic secondary lesion of Wingfield is capable of complete disappearance, or, alternatively, if it does disappear whether it can be tuberculous, but in my experience these lesions can and do disappear without leaving any radiological trace. Admittedly, Wingfield's "attractive theory" is lacking in definite proof, but so also is the differentiation of acute simple pneumonitis from bronchopneumonia. Furthermore, it is not generally accepted, as is suggested by Dr. Gill, that "pulmonary lesions containing tubercle bacilli heal by fibrosis, leaving scar tissue which can readily be detected by x-ray examination." While this is true of gross lesions it is quite inapplicable to many small tuberculous deposits of the tertiary or granulomatous type (usually described as "infiltrative"). It is not uncommon to see small patches of infiltration disappear completely in serial radiographs.

There must also be offered criticism of the statement that "those tuberculous pulmonary lesions, believed to be allergic, which occur in childhood invariably leave recognizable foci on healing—for example, Ghon lesions." If by "recognizable" radiological recognition is implied the statement is untrue, for although over 90 per cent. of us have had a Ghon focus, under 5 per cent. will show radiological evidence of it; if pathological recognition is meant, the comparison has no point in the differential diagnosis of pneumonitis, "a disease in which no fatalities have as yet been recorded." It is surely a postulate of the theory of bacterial allergy that the state of allergy cannot be established until the primary infection has been well entrenched if not actually overcome. For this reason the inclusion of the universally accepted primary Ghon focus amongst its own allergic sequelae is manifestly absurd.—I am, etc.,

G. S. ERWIN.

X-Ray Film Developing Box

SIR,—Mr. B. Whitchurch Howell (*Journal*, March 19, p. 650) is apparently completely unaware that the process of development which I described in the *Journal* of March 12 (p. 569) dates back in its essentials to the "Ambrotype," the immediate successor of the "daguerreotype," otherwise he would certainly not attempt to credit any particular radiographer with its discovery. The modern version of this process, which originated in the 'sixties, is the ferrotype, well known at seaside resorts. No medical man who happens to be a member of the Royal Photographic Society, as I am, would ever dream of calling one-solution-processing an "invention" just because it is applied to x-ray films. As I said in my original note, we merely

attempted to modify an old process to meet a modern need; this, as the figures show, we have certainly succeeded in doing.—I am, etc.,

Manchester, March 19.

ROBERT G. W. OLLERENSHAW.

Colleagues in Austria

SIR,—In view of recent events we, the undersigned members of the medical profession, desire to express our alarm at the possible fate of our colleagues in Austria. There are in that country many revered physicians and surgeons who are likely to fall into disfavour with the National Socialist Government, either on account of their medical or social views or on account of their belonging to the Jewish race. Judging from what has happened in Germany in the past we are afraid that serious discrimination will be exercised against them and that even the chance to leave a country which is no longer hospitable to them may be refused.

We beg our colleagues in all countries to watch the progress of events with the closest attention and to do all in their power, whether by public protest or by public or private assistance, to stand by any members of our profession who may suffer hardship under the new regime.—We are, etc.

Obituary

D. L. STEVENSON, M.A., M.B.

We regret to announce the death on March 12 of Dr. David Lyon Stevenson at his home in Larkhall, Lanarkshire. He was born in 1871, and from Glasgow High School went to study medicine at the University of Glasgow, graduating M.A. in 1892 and M.B., C.M. in 1896. For the past forty years he had practised in Larkhall and district. Throughout that time he was a popular and deeply respected figure, and his excellent work for the medical profession was well known far beyond Lanarkshire.

Dr. Stevenson joined the British Medical Association in 1912, and was chairman of the Lanarkshire Division in 1929-30; he represented his Division at the Annual Representative Meeting on many occasions, and was recently a member of the Scottish Committee and of the Central Council. He had been a member of the Insurance Acts Committee and of the Insurance Acts Subcommittee for Scotland continuously from 1921 onwards, and was for a time secretary of the Lanarkshire Panel Committee. Dr. Stevenson also took a prominent part in the public life of his district: he was a Justice of the Peace and had been vice-chairman of the Larkhall School Board and chairman of the School Management Committee. His interest in the educational welfare of his younger neighbours never ceased, and in practical proof of this he presented annually for the past thirteen years a gold medal to the dux of Larkhall

the wart, which is then punched out, using a rotatory movement of the "borer." When a sufficient depth is reached it will be found that on withdrawing the instrument the wart stands out two or three millimetres from the surface of the foot and can be pulled out with forceps, the base being cut through with fine curved scissors or a tenotomy knife. The usual dressing is then applied. Another method, more prolonged, is to apply a few crystals of salicylic acid to the moistened wart, cover with elastoplast, and leave for a week. Bandaging the foot will prevent the plaster from curling off. The wart and its immediate surroundings are white and mushy on removal of the elastoplast. The debris is curetted and the treatment repeated. The wart completely comes to the surface after four or five applications, and is finally completely curetted away. One advantage of this method is that there is no post-operative pain.—I am, etc.,

R. F. WYNROE,

Flight Lieutenant R.A.F.

Cranwell, March 15.

Pasteurization of Milk

SIR,—Dr. James Kirkland, in the *Journal* of February 5, states that "the *B. coli* found in pasteurized milk are almost invariably of the non-faecal type." If the *B. coli* from manure survives pasteurization, it is obvious that the contaminated milk has not been effectively pasteurized. This raises the question whether *B. coli* can survive a higher temperature than the tubercle bacilli. I would like to know.

My chief objections to pasteurized milk are that it gives a false security and sterilizes the stimulus to produce clean milk and T.T. milk. Moreover, would it not have been advisable in the B.M.A. advertisement to have warned the public that in 1927 an outbreak of typhoid in Montreal was traced to a typhoid carrier working in a pasteurizing plant? There were 5,014 cases and 500 deaths.

Again, with all respect to those who claim to speak on behalf of 37,000 doctors, I cannot understand why no weight is given to the opinion of Dr. Chalmers Watson, one of our leading dietitians, that pasteurization affects the nutritive value of milk apart altogether from its vitamin content. The Economic Advisory Council's Committee on Cattle Diseases have reported that pasteurization has a destructive effect on vitamins C and D in milk.

Sir Leonard Hill's letter in to-day's *Journal* is further proof that the shadow of depopulation and national decline is looming in the near future. Milk is a staple food, and before pasteurization is adopted as a national policy I suggest that it would be wise to test the effects of pasteurization on the fertility vitamins. This could be done by feeding one group of rats on fresh milk and another group on pasteurized milk. It would be interesting to know if this affected their fertility. Let us experiment on animals before experimenting on the nation.—I am, etc.,

London, W.8, March 12.

HALLIDAY SUTHERLAND.

Multiplicity of Special Diplomas.

SIR,—Recently an advertisement appeared in the medical press inviting medical men to sit for the examination of the Fellowship of the British Association of Radiologists, the examination being limited to registered medical practitioners who have held a diploma in radiology for two years. I am not a radiologist nor do I intend to become one, but I feel that it is high time that some medical man rose to protest against the absurd number of diplomas

and examinations that are being introduced and to which we are allowing ourselves to become subjected.

It is not many years since the holding of a recognized qualifying degree or diploma and the possession of suitable experience under a competent member of our profession was all that was required to obtain an appointment in a hospital or other medical institution. Alas! those days have passed away. The fact that one is widely experienced in any branch of the profession or can produce recommendations and testimonials from the leaders of any particular branch of medicine is useless, and what is required is the possession of the fashionable series of letters after one's name. There was a time when the letters M.D. were the hall-mark of medical respectability, but fashions change, and to-day M.R.C.P. or F.R.C.S. hold the field; it is the letters that matter, what they signify seems unimportant. I know of two cases where appointments to ophthalmic surgeons' positions were made because of the possession of the magic symbol F.R.C.S., though in one case it was obtained in gynaecology and obstetrics and in the other with oto-rhino-laryngology as the main subject, in neither case ophthalmology being included; for, as these Fellows told me, the examiners in ophthalmology held ideas different from their own and certainly would not pass them.

The last few years have seen the foundation of the College of Obstetricians and Gynaecologists and the British Association of Radiologists. No one can dispute the desirability of these societies so long as they limit their activities to promoting the growth of knowledge in their specialty, but when they start by presenting each foundation member with an imposing series of letters to be attached to his name, and then setting up an examination board to present these same letters to those who were not smart enough or old enough to apply for them at the beginning, one wonders whether they are not exceeding their usefulness. This is not all, for the College of Obstetricians and Gynaecologists, which yet had hardly recovered from its own birth pains, is already attempting to limit appointment to certain positions to its own members or fellows, while the Association of Radiologists, though not yet taking this step, sets itself up to re-examine those who already possess a recognized diploma in radiology.

Medicine is a rapidly growing subject, and the possession of specialist knowledge is undoubtedly of value, but are the holders of the diploma in child health, the diploma in anaesthetics, the diploma in psychological medicine, in tuberculosis, in tropical medicine, or in radiology better than their brethren who have practised these subjects for years and have never bothered to collect the fashionable letters? Personally I doubt it. Our sister profession of Law does not insist on an LL.D. before taking silk, or a D.C.L. for a seat on the bench. Yet the legal system does not seem to suffer. British medicine alone seems to find the multiplicity of special diplomas necessary; in America and on the Continent, where medical science is equally advanced, a primary medical qualification and adequate experience appear to be all that is required for senior medical appointments.

It will of course be argued that the possession of a postgraduate diploma is merely to show that a certain standard of knowledge has been obtained, and that appointments are made on previous experience. Of late the results of even the simplest examinations have been shown to be entirely fallacious as a test of knowledge, and it has never been even suggested that any examination is a test of ability. Yet the medical profession, which should be the leader of modern thought, has multiplied

UNIVERSITY OF LIVERPOOL

The Council of the University has appointed Dr. Rupert Montgomery Gordon, director of the Sir Alfred Lewis Jones Research Laboratory, Freetown, Sierra Leone, to the Dutton Memorial Chair of Entomology, in succession to Emeritus Professor W. S. Patton, who retired in December. Professor Gordon graduated M.B., B.Ch. at Trinity College, Dublin, in 1916, and after serving in the war took the diploma in tropical medicine and worked on the Amazon. In 1924 he was transferred to Freetown. Last year he was awarded the Chalmers Gold Medal by the Royal Society of Tropical Medicine and Hygiene for research in tropical medicine and hygiene.

The following candidates have been approved at the examinations indicated:

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.—Part A: G. E. Church, N. A. Lawler, W. Niven, F. Pygott.

DIPLOMA IN PUBLIC HEALTH.—Part I: S. Ball, A. Cathcart, M. B. Conzanon, L. R. L. Edwards, A. J. Gill, A. L. Smallwood, Margaret C. Winter.

DIPLOMA IN TROPICAL MEDICINE.—F. Bastawros, P. J. Bourke, O. Einstein, N. Q. Hesse, F. Jacusiel, K. Jilani, *J. Kay, E. Kohlschütter, J. L. Lanceley, B. Nyan.

DIPLOMA IN TROPICAL HYGIENE.—J. L. Dales, V. G. Patwardhan.

* Recommended for the Milne Medal.

Medico-Legal

LIABILITY OF THE RADIOLOGIST

A Mock Trial

The Society of Radiographers held a mock trial at Cowdroy Hall on March 19 entitled "Martin v. The Northside Hospital and Violet Wray," in order to indicate the possible liability at law of a radiographer making a diagnostic exposure. The proceedings were written by Dr. J. Duncan White and Dr. E. Rohan Williams, and the play was produced by Mr. Cuthbert Andrews.

"Mr. Crawford Snoop, K.C." (Mr. Andrews), for the plaintiff, said that on July 12 the plaintiff's youngest child had fallen and hurt his arm. She had taken him to the Northside Hospital, where the arm had been x-rayed. The mother had received a shock and had been burned on the head and her mental equilibrium had been impaired. She had had three weeks' holiday at Southend-on-Sea. She claimed damages and her expenses.

"Sir Archibald Head" (Dr. Duncan White) submitted on behalf of the defendants that there was no case against the hospital, as the governors were not responsible for properly qualified assistants. The other defendant held the certificate of membership of the Society of Radiographers. She had taken all proper precautions in carrying out her work.

"Mr. Justice Likely" (Mr. J. A. Crowther) cited *Hillier v. St. Bartholomew's Hospital* (1909, 2 K.B. 820) and *Strangeways v. Lesmere v. Clayton* (1936, 1, E.R. 484), and applied the words of Lord Justice Kennedy to all experts exercising skill in work in which the governors could not properly interfere. Radiographers were, he said, included, and he dismissed the hospital from the action, but ruled that the Court must hear evidence of fact in the case against "Miss Wray."

"Mrs. Maria Martin" (Miss A. E. Madden), the plaintiff, a widow aged 29, said that she had felt a dreadful pain and known no more. She had awakened with an awful pain in her head. Defendant had given her a restorative, and put a bandage on her head. Since then she had "been all to pieces," and had not had a good night's sleep for months. "It was like as if some of them rays 'ad got into me inside and I'm all spasms," she added. Cross-examined, she admitted she had never consulted a doctor; she did not believe in doctors. Defendant had told her to keep quite still during the examination.

"Miss Amelia Hobbs" (Miss M. V. Sprague), a friend of the plaintiff, testified to the change in her friend after the shock; she "seemed all broke up." In cross-examination she admitted that she also had gone to Southend.

"Dr. O. H. Maloney" (Dr. Rohan Williams), honorary radiologist to the Northside Hospital, testified to the character and reliability of the defendant.

"His Lordship" remarked that witness's catalogue of the requirements for a good radiographer sounded like an amalgamation between the Admirable Crichton and a member of the angelic chorus.

"Miss Violet Wray" (Miss M. M. T. Aleyn), the defendant, described her training and experience. She had told plaintiff to sit on a chair, hold the child still, and sit still herself. Plaintiff had jumped forwards and upwards at the moment of exposure and sustained mild burning on her scalp and beneath her suspender button. The house-surgeon had examined her and said she might go home.

Counsel for the plaintiff suggested that the use of 100 mA was dangerous, but witness replied that he was misinformed, as the only danger was to the tube, and not to the patient.

"Professor Nathaniel Percy Littlar" (Dr. G. W. C. Kaye), an expert witness, expressed the opinion that defendant's handling of the case had been in accordance with usual practice. Risks were inseparable from x-ray work. He explained to the Court the mechanism of production of electrical shock, while the judge slept.

"His Lordship," summing up, said that the action was unique; there had been no case before the courts in which the defendant had been a radiographer. The jury had to decide whether or not defendant had been negligent. He asked whether it was wise to allow plaintiff to hold the child during the examination, since she could have no acquaintance with the risks of x rays.

The jury returned a verdict for the defendant.

The production and acting were first-class; the atmosphere was realistic and the situations were amusing. With improvised scenery Mr. Andrews nevertheless suggested very skilfully the atmosphere of the High Court, and in certain details, such as the demeanour of the attendant and the completely detached absorption of the associate in his own clerical work during the proceedings, he gave evidence of careful observation. The legal aspect, however, was rather deplorably scamped. Perhaps the position of the hospital was not necessary for the purpose of the argument, and its discussion would certainly have prolonged the play, but the grounds for dismissing the hospital from the suit were very inadequate. The charge of negligence against the radiographer was not supported by any evidence at all. Her qualifications and duties were, however, clearly set out in the evidence, and the necessity for some form of collective legal defence was stressed by the judge in his summing-up.

The Services

COMMISSIONS IN THE R.A.M.C.

Applications from medical men for appointment to commissions in the Royal Army Medical Corps are invited by the War Office. Candidates will be selected for commissions without competitive examination, and will be required to present themselves in London for physical examination and interview on or about April 22. They must be registered under the Medical Acts, and normally must not be over the age of 28 years.

Successful candidates will, in the first instance, be given short service commissions for five years. During the fourth year of this period they will be given the opportunity of applying for permanent commissions in either the Royal Army Medical Corps or the Indian Medical Service. Those not selected will retire on completion of five years' service with a gratuity of £1,000.

Full particulars of the conditions of service and emoluments, also forms of application, may be obtained on application, either by letter or in person, to the Assistant Director-General, Army Medical Services, the War Office, London, S.W.1.

NAVAL MEDICAL COMPASSIONATE FUND

A meeting of the subscribers to the Naval Medical Compassionate Fund will be held on April 22, at 3.15 p.m., at the Medical Department of the Navy, Admiralty, S.W.1, to elect six directors of the Fund.

Academy. A noted athlete in his younger days, he played cricket for his university and football for Queen's Park F.C. He was also keen on bowls and lawn tennis, and regularly visited Wimbledon to watch the championships. He is survived by his wife and one son, with whom deep sympathy is felt in their bereavement.

By the death of JOHN MCALISTER BOYD on March 11 Wigan has lost one of her outstanding personalities and medicine a pioneer of those ethical rules and unwritten social observances which have unified the local profession as we see it to-day. Born at Aghadowey, Co. Derry, in 1867, he was educated at the Coleraine Academical Institution, Magee College, Londonderry, where he was the Ironmongers' Scholar, 1885-7, Queen's College, Cork (medical exhibition, 1889), and Queen's College, Belfast, graduating B.A. in 1892 and M.B., B.Ch., B.A.O. of the Royal University of Ireland in 1897. He came to Wigan in 1898, shortly afterwards joining the British Medical Association, of which he was a staunch supporter. He was president of the Wigan Medical Society. A sportsman in the best sense of the term, "J. M. B." played rugby for Magee and Cork Colleges as a student, and later took up golf, at which he was no mean performer. A lover of the classics and good literature, erudite, and a brilliant raconteur with a charming manner, it is not surprising that John Boyd was greeted with acclamation by his vast circle of friends. A sound clinician, his aptitude extending to the literature of his profession, he was well versed in modern medical thought. He will be greatly missed by his patients, among whom were many who deemed it an honour to be called his friend. He married in 1898 Margaret Elizabeth, only daughter of the late Francis Furey of Killyleigh, Co. Down, who survives him.—W. E. C.

We regret to report the death, on March 2, of Dr. THOMAS BRETT YOUNG, who had practised in Halesowen, North Worcestershire, for over fifty years. Born in 1856, he was a medical student at Queen's College, Birmingham, obtaining the diplomas L.R.C.P., L.R.C.S.Ed., and L.M. in 1883 and the M.R.C.S.Eng. five years later. He graduated M.D.Brux. in 1888. Dr. Brett Young went from Somerset to Halesowen, and was appointed first medical officer of health to that town when it became the centre of a rural district forty-three years ago. He was a certifying surgeon under the Factory Act for many years, tuberculosis officer for the Halesowen area of Worcestershire, and contributed largely to the success of the child welfare clinics in the town. He was for a time warden at the parish church, and was interested in Freemasonry. He had been a member of the British Medical Association for thirty-nine years. Despite increasing illness during his latter years he continued actively at his work, being widely popular and highly respected. He was the father of the well-known novelist, Francis Brett Young, who graduated in medicine in 1906, and of the late Eric Brett Young, also an author. Dr. Thomas Brett Young, who had married twice, leaves a widow.

Dr. WILLIAM HENRY DAVIS, formerly of Wrekenton, whose death has been reported from Carlisle, received his medical education at Newcastle-on-Tyne, and qualified L.S.A. in 1880. Nearly fifty years ago he followed his brother in the practice founded about 130 years earlier in Wrekenton and Low Fell by their grandfather. He continued to practise there until 1934, when he retired and went to live at Carlisle with his married daughter. He joined the British Medical Association in 1893. While devoting himself to the responsibilities of the large private practice which extended through Wrekenton, Low Fell, and Gateshead-on-Tyne, Dr. Davis found time to interest himself actively in the work of the Church of England and the fortunes of the Conservative Party in politics. He was buried at Lamesley on March 8.

Mr. FREDERICK SHANN, consulting surgeon to the York County Hospital, died on March 8 at Farnham, Knaresborough, aged 88. After studying medicine at Cambridge and St. George's Hospital he took the M.R.C.S. in 1875 and the L.R.C.P. in 1876, and served as clinical assistant at the Brompton Hospital, house-physician at St. George's, and house-surgeon at the Seamen's Hospital, Greenwich. He practised in York for many years, and in 1902 was appointed sheriff of the city, and two years later a magistrate. Mr. Shann served with the 1st Volunteer Battalion of the West Yorkshire Regiment and attained the rank of surgeon lieutenant-colonel, receiving the Volunteer Officers' Decoration. He retired from active work in 1927.

Dr. THOMAS WILLIAM SCALE, who died at Aberdare, South Wales, after a short illness, aged 82, had been a member of the British Medical Association for nearly sixty years. Born at Merthyr Tydfil on April 12, 1856, the son of Edward W. Scale, he spent his schooldays at Alston College, Lancashire, and studied medicine at the Middlesex Hospital and Newcastle-on-Tyne. He became L.S.A. in 1879, M.R.C.S. in 1880, L.R.C.P. in 1897, and M.D.Durh. in 1898. Before settling in practice in Glamorganshire, Dr. Scale had been house-physician at the Middlesex Hospital and assistant medical officer at the Royal Portsmouth Hospital. He was for many years surgeon to the Aberdare General Hospital.

Dr. CHARLES KIRK TOLAND, who died suddenly on March 14 after a medical meeting at Leicester, was in practice at Ullesthorpe, Rugby. He had received his medical education at the University of Glasgow, where he graduated M.B., C.M. in 1895, and proceeded M.D. in 1912. He was surgeon to Chief Baron Smith's Almshouses, and had previously been on the medical staffs of the Dunstable Isolation Hospital and the ophthalmic department of the London County Council School Treatment Centre. He joined the British Medical Association in 1910, and was president of the Leicester and Rutland Branch during the current year. He contributed a report of a case of ruptured kidney to the *British Medical Journal* in 1897.

The death is announced of the Swedish ophthalmologist Professor HANS GERTZ of the Karolinska Institute in Stockholm. He was born in 1876. Much of his research as an ophthalmologist was concerned with purely physiological problems, and he was particularly interested in the mechanism of the movements of the eyes. Special mention should be made of his investigation of the mechanism enabling the eyes to remain looking at a certain object in spite of various movements of the head.

Universities and Colleges

UNIVERSITY OF OXFORD

Mr. G. R. Girdlestone, F.R.C.S., Nuffield Professor of Orthopaedic Surgery, has been elected to a Supernumerary Fellowship at New College.

UNIVERSITY OF LONDON

UNIVERSITY COLLEGE

Bucknill Scholarship

The examination for the Bucknill Scholarship, value 160 guineas, and for two exhibitions, value 55 guineas each, will begin on May 9. The subjects for the examination are chemistry, physics, botany, zoology, and English essay. The scholarship and the two exhibitions are tenable at University College, London. Entry forms should be obtained from the secretary of University College, Gower Street, W.C.1, and returned not later than April 27.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended March 12, 1938.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 125 great towns (i) in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns (ii) in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1938					1937 (Corresponding Week)					1929-37 (Median Value Corresponding Weeks)

* 168 cases in Belfast alone.

† After October 1, 1937, puerperal fever was made notifiable only in the Administrative County of London.

† Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

DEATHS IN THE SERVICES

Major DONALD JOHN MACDOUGALL, M.C., R.A.M.C., died suddenly at Bombay on February 18, aged 46. He was born on April 28, 1891, and was educated at Glasgow, where he graduated M.B., Ch.B. in 1915. Immediately afterwards, on October 28, 1915, he took a temporary commission as lieutenant in the Royal Army Medical Corps, became temporary captain after a year's service, and took a permanent commission as captain from June 1, 1920, and became major on October 28, 1927. He served in the war of 1914-18, in which he received the Military Cross.

Colonel WILLIAM ADAIR QUAYLE, Madras Medical Service (ret.), died at Budleigh Salterton, Devon, on March 16, aged 82. He was born on December 9, 1855, the son of Francis Quayle, farmer of Ballyculter, County Down, was educated at Queen's College, Belfast, and graduated M.D., M.Ch. in 1877. He entered the Indian Medical Service as surgeon on March 30, 1878, attained the rank of colonel on April 1, 1908, and retired on April 30, 1911. He had been a member of the British Medical Association for forty-three years.

Lieutenant-Colonel CHARLES NORMAN BENSLEY, Bengal Medical Service (ret.), died at High Wood, Cookham Dean, on March 16, aged 74. He was born at Raipur, Central Provinces, India, on October 20, 1863, the son of Assistant Surgeon, afterwards Surgeon Major, C. E. N. Bensley, I.M.S., and was educated at Edinburgh, where he graduated M.B., C.M. in 1885. He entered the Indian Medical Service as surgeon on September 30, 1886, became lieutenant-colonel after twenty years' service, and retired on November 12, 1911. During the war of 1914-18 he rejoined for service in India on February 19, 1915, and served for two years.

Colonel CECIL BIRT, late R.A.M.C., died at Sydenham on March 18, aged 78. He was born at Leamington on February 10, 1860, the son of the late Dr. Thomas Birt, was educated at Birmingham and at University College, London, and took the M.R.C.S. in 1881 and the L.R.C.P. in 1882. After filling the post of surgical assistant at the General Hospital, Birmingham, he entered the Army as surgeon on August 2, 1884, received a brevet lieutenant-colonelcy on August 22, 1902, for service in South Africa, became lieutenant-colonel on August 2, 1904, and colonel on January 1, 1914, and retired on December 26, 1917. He served in the Sudan campaign of 1885, at Suakin (medal with clasp, and Khedive's bronze star); in the Chitral campaign of 1895, with the relief force (medal with clasp); in South Africa in 1901-2, in operations in Cape Colony, the Orange River Colony, and the Transvaal (mentioned in dispatches in the *London Gazette* of July 29, 1902, Queen's medal with five clasps, and brevet of lieutenant-colonel), and in the war of 1914-18. He won the Alexander Memorial Gold Medal in 1894 and 1897.

EPIDEMIOLOGICAL NOTES

Diphtheria and Scarlet Fever

Compared with the figures recorded last week, there has been a decrease in the incidence of diphtheria except in Northern Ireland, where 42 cases were notified, compared with 38 in the previous week; the number of deaths was also lower, except in Scotland, where 9 were recorded, compared with 7 in the previous week. Despite these reductions, the figures for England and Wales remain much higher than the median value for the last nine years, while for London they are slightly lower. On the other hand, scarlet fever appears to be increasing in prevalence both in England and Wales and in London. As in respect of diphtheria, figures for England and Wales are greatly in excess of the median value for the corresponding weeks of the last nine years, while in London they are appreciably less.

Measles

In the 125 Great Towns there were 50 deaths from measles, compared with 44 in the previous week; of these 13 occurred in London, 1 less than in the previous week. Other centres from which deaths were reported are: Liverpool 7 (3), Sheffield 4 (0), Manchester 3 (1), Croydon 2 (0), Bristol 2 (1), Plymouth 2 (2). The epidemic of measles in London continues to spread; 2,521 cases were reported in the L.C.C. elementary schools during the week

under review, compared with 2,165 in the previous week, and the average daily admissions to the L.C.C. fever hospitals were 101, compared with 86 in the previous week, while the number of cases of measles under treatment in these hospitals on Friday, March 11, was 1,892, compared with 1,542 in the previous week. On the same day there were under treatment in the L.C.C. fever hospitals 1,275 (1,277) cases of diphtheria, 840 (819) of scarlet fever, and 271 (277) of whooping-cough. The figures in parentheses refer to the numbers in the previous week. Figures are available of notifications of measles for the week ended March 12 in the metropolitan boroughs in which notification is in force: Battersea 143, Bermondsey 54, Finsbury 27, Fulham 51, Greenwich 68, Hampstead 69, Lambeth 355, St. Pancras 172, Shoreditch 17, Southwark 207, Stepney 51. In Scotland 1,718 cases were notified, compared with 1,747 in the previous week; the figures in Glasgow being 1,188 (11), Edinburgh 105 (1), Paisley 79, Dundee 140, Aberdeen 51. The figures in parentheses denote the deaths. In Northern Ireland there were 171 cases, compared with 237 in the previous week; the figures for Belfast were 168 against 217, while deaths were 18, compared with 13 in the previous week. During the week one death from measles was recorded in Dublin, the same number as in the previous week.

Small-pox

It is reported in the Press that a man suffering from a mild form of small-pox was admitted to the isolation hospital at Gravesend on March 21.

Reports from Hong Kong indicate that there is at present a small-pox epidemic of some magnitude. The disease is almost entirely confined to the natives, only 3 European cases so far being reported, 1 of which was fatal. In the week ended March 12 there were 214 cases (128), compared with 185 (188), 164 (132), 228 (199), in the three weeks immediately preceding. The figures in parentheses refer to deaths in the same week. The first case was notified on November 24, 1937, and from that date until February 2, 1938, the total number of cases notified was 259, with 159 deaths. An energetic vaccination campaign has been in progress since the beginning of the outbreak. Minor small-pox epidemics are usual in the cold season in Hong Kong. In the six-year period 1932-7 the average number of cases in each year was 190, varying from 566 in 1933 to 23 in 1936. The increase of cases this season is due mainly to the large influx of refugees from other parts of China, with consequent overcrowding of urban areas in and around Hong Kong.

Enteric in Spain

The Sanitary Administration of the Spanish Republic at Barcelona has prepared a table in which for a certain number of provinces, occupied wholly or in part by the Republican troops, a comparison has been made between the number of cases and deaths from typhoid fever in 1935 and 1937. From this has been calculated the rates of morbidity and mortality per 100,000 inhabitants during the two years, showing the increase or decrease in these rates for 1937 as compared with 1935. Among the 19 provinces from which data were available 10 showed in 1937 increases and the remaining 9 decreases in typhoid morbidity as compared with 1935, while mortality was seen to have increased in 13 of the provinces and decreased in 6. It was pointed out that the figures can only be regarded as approximate on account of the exceptional circumstances obtaining throughout Spain on account of the civil war.

Typhus in Africa

Typhus seems to be on the increase in Morocco. There were 418 cases notified in the week ended March 5, compared with 298 in the previous week, the highest incidence being in Marrakesh 98, Casablanca 29, Chaouia 54, Rabat 30. In the same week there were in Tunisia 100 cases, compared with 59 in the previous week, and in Egypt 36 cases were recorded.

Home Secretary to instruct the police not to bring actions of this kind against them or, alternatively, to take steps to get the law altered.

Mr. GEOFFREY LLOYD replied that the law relating to the obstruction of the highway applied to all vehicles alike. The Home Secretary had no authority to advise the police to refrain from enforcing it against any particular class of the community, nor did he on present information see grounds for the introduction of legislation on the lines suggested. So far, however, as was consistent with their duty to prevent obstruction of the highway, the police already endeavoured to allow a reasonable latitude to drivers who had good reason to leave their vehicles waiting on the streets for short periods.

Marriage Allowances for Naval Officers

Presenting the Navy Estimates on March 17, Mr. SHAKESPEARE said the Admiralty had re-examined the claim of the married officers. In future marriage allowance would be payable to the married officer at the age of 30, and was applicable to all officers up to the rank of captain in the Navy or up to the rank of lieutenant-colonel in the Royal Marines. A reduction of 2s. a day would be made in the full pay of all officers of these ranks with the exception of the few lieutenants concerned. Marriage allowance for a captain R.N. would be 5s. 6d. a day and for other commissioned officers 4s. 6d. The allowances for children would be 2s. a day for the first child and 1s. a day for each subsequent child. The Admiralty had to reserve for further consideration the applicability of the present scheme, with or without some special modification, to the medical branch. He sympathized with the natural disappointment which all Royal Naval medical officers would experience when they heard this statement. Every effort was being made to arrive at an equitable arrangement for all naval medical officers at a very early date.

Extent and Cost of Vaccination

On March 21 Mr. GROVES asked the Minister of Health if he would supply particulars for each of the last five years for which complete figures were available of the number of public vaccinations and revaccinations, the expenditure of local authorities on vaccination, and the expenditure on the Government lymph establishment.

Sir KINGSLEY WOOD replied that the information desired was as follows:

Public Vaccinations and Revaccinations (England and Wales)

Year ended September 30	Public Vaccinations	Revaccinations
1932	207,543	16,624
1933	189,857	9,628
1934	184,137	14,802
1935	183,917	9,267
1936	176,618	11,434

Net Expenditure on Vaccination of All Local Authorities (England and Wales)

	£
1931-2	136,714
1932-3	136,365
1933-4	128,339
1934-5	125,646
1935-6	126,775

Net Expenditure of Government Lymph Establishment

	£
1932-3	12,583
1933-4	11,752
1934-5	11,492
1935-6	12,263
1936-7	12,069

Water Supply from Addington Well, Croydon.—On March 21 Mr. GROVES asked the Minister of Health whether the water from the Addington well at Croydon was still under suspicion, and, if so, what was the cause of the suspected contamination of the water. Sir KINGSLEY WOOD replied that it was considered that, in view of the situation of this well, the water should, as a precautionary measure, be subjected to an effective method of treatment.

Medical News

Mr. J. E. H. Roberts will read a paper on "The Surgical Treatment of Pulmonary Cavities" before the North-Western Tuberculosis Society in the physiology theatre of the Medical School, Manchester University, on Thursday, March 31, at 3.15 p.m. Medical practitioners interested are cordially invited to attend.

A sessional meeting of the Royal Sanitary Institute will be held at Yeovil Council Chamber on Friday, April 8, at 5 p.m., when discussions will take place on "Milk and Pasteurization," to be opened by Sir William Savage, and on "The Administration and Management of Housing Sites," to be opened by Mr. Ivor F. Shellard.

The dinner-discussion arranged by the West London Medical-Chirurgical Society for April 1 has had to be postponed until Friday, April 8, at 7.45 p.m. Dr. J. F. Halls Dally will introduce the discussion on "Recent Advances in Rheumatism." Dr. W. S. C. Copeman will show a cinematograph film, and Dr. C. B. Dyson will speak on serology. The place of meeting is the De Vere Hotel, Kensington Road, W.

The thirty-first congress of the Italian Society of Dermosyphilography will be held in Rome from April 22 to 24, when the subjects for discussion will be: (1) foci and dermatoses; (2) foci and the urogenital apparatus; and (3) non-gonococcal urethritis. Further information can be obtained from the secretary, Professor V. Montesano, Via Campo Marzio 69, Roma.

The seventh French Congress of Gynaecology will be held at Nice from April 19 to 23, when the subject for discussion is gonorrhoea in the female. The congress will be followed by an excursion to Corsica from April 24 to 28. Further information can be obtained from Dr. P. Gasquet, 47, Boulevard Victor-Hugo, Nice.

The fourteenth Congress of the German Pharmacological Society will be held in Berlin from April 24 to 28, when the following subjects will be discussed: local anaesthesia, carcinogenic substances, and coffee and caffeine. Further information can be obtained from Professor Flury of Würzburg, the president, or Professor Behrens of Kiel.

The Bath International Conference on Rheumatic Diseases will open on the evening of Thursday, March 31, and will continue till midday, April 3, under the presidency of Lord Horder. Professor F. R. Fraser, Sir Humphry Rolleston, and Sir Walter Langdon-Brown are presidents of sessions. There is no fee for participation in the congress, but anyone wishing to attend should communicate immediately with the honorary secretary, 6, The Circus, Bath in order to book accommodation and obtain the programme and invitations to the social functions.

On March 3, at the New York Academy of Medicine, Dr. James Alexander Miller, the president, presented the Academy medal to Dr. Bela Schick on the occasion of the twenty-fifth anniversary of the publication of his work on immunity in diphtheria. The Schick test, first described in the *Münchener medizinische Wochenschrift*, 1913, 60, 2608, "laid the basis for the present-day effective campaign of prevention against this dreaded disease." Dr. Schick, born at Boglar, Hungary, in 1877, took his M.D. at Graz in 1900, and, after a distinguished career in Vienna, went to the United States of America in 1923 as paediatrician-in-chief at the Mount Sinai Hospital, New York.

Dr. Burgess Barnett, who was curator of reptiles under the Zoological Society of London from 1930 to 1937, has been appointed superintendent of the Rangoon Zoological Gardens, and will take up his new duties in June. Dr. Barnett intends to continue his research work on snake venom and its applications to medical practice.

Medical Notes in Parliament

In the House of Lords on March 22 the National Health Insurance (Amendment) Bill was read the third time and passed. The Housing (Financial Provisions) Bill was read a second time.

Unemployment and foreign policy were debated by the House of Commons this week on the Consolidated Fund Bill and the Estimates for the Defence Services were debated on report.

On March 22 accounts of the income and expenditure of the General Medical Council and of the Branch Councils for 1937, and also of the Dental Board of the United Kingdom for the same year, were presented to Parliament. There was also laid on the table a return of the visits made and patients seen by the Commissioners in Lunacy during the six months ended December 31, 1937.

The Registration of Stillbirths (Scotland) Bill passed through a Standing Committee of the House of Commons, with one amendment, on March 17.

The Children and Young Persons Act (1933) Amendment Bill was reported to the House of Commons on March 22 from standing committee with amendments and with its title changed to the Children and Young Persons Bill.

In the House of Commons on March 22 Mr. Elliot presented a Bill to amend the law relating to marriage in Scotland.

Infanticide Bill

In the House of Lords on March 22 Viscount DAWSON OF PENN moved the second reading of the Infanticide Bill. He said that the intention of the Bill was to secure recognition by Parliament that in certain circumstances the killing of infants was provoked by illness and not always by criminal intent. The subject had vexed the minds of lawyers and the public for seventy years. In 1861 a Bill created the offence of concealment of birth. In 1909 a Bill passed through the House of Lords providing that should a judge think proper he could direct a jury to acquit a defendant of murder and convict that person of manslaughter, and the sentence was left to the judge. Even up to 1909 there was no comprehension that there was a group of cases in which the cause was illness rather than criminal intent. In 1922 there came the Infanticide Act, a more far-seeing measure. Thus theory lagged behind practice by no less than sixty years. It could not be in the interests of justice that courts should be forced to find loopholes to get away from Acts of Parliament, and, when they could not find them, be forced to put up wretched people on charges of murder and pass sentences of death, which both judges and juries knew would not be carried out.

The Act of 1922 provided that in cases where at the time a mother caused the death of her child she had not fully recovered from the effects of giving birth to a child, and the balance of her mind was thereby disturbed, she would be guilty of manslaughter. There was, however, no definition in the Act of what was meant by a "newly born" child. In his Bill the term "newly born" had been omitted and a time-limit of a year inserted. The second clause of the Bill gave a jury power to bring in a verdict of infanticide on their own initiative. When a defendant appeared in a court of first instance it was neither fair nor necessary that she should be remanded to prison. Where possible bail should be allowed, but where that was not possible she should be remanded to a hospital or home. It was damaging to such a defendant and to her prospects of recovery that she should be remanded to prison. In a large proportion of these cases, except in the severe ones, there was a complete recovery. Forty-two per cent. of the female admissions to Broadmoor were for child-destruction, and half of these cases recovered. It was an unfortunate thing that those women should have the Broad-

moor stamp. It directed attention to the desirability of treating them as cases of illness.

In their desire to be impartial the House must be careful not to provide means of escape for the murderer of the unwanted child. That was one reason why he had limited the provisions of the Bill to one year. A group of influential people thought he ought to have extended the period beyond one year. It was rare to find cases of insanity following childbirth which did not recover within a year. The Bill implied that certain offences could be due to mental illness, and when that illness amounted to irresponsibility for the offences charged the patient should neither be punished nor dubbed as a lunatic, but should be bound over for appropriate treatment. It would be a practice more in harmony with present-day thinking and sound humanity.

Lord SNELL said the Labour Party gave the Bill their general support, but that if a patient of this kind was sent to a hospital they were concerned to know what sort of hospital it would be. A criminal lunatic asylum was not the right place, nor was a mental hospital. The MARQUESS OF CREWE, Lord ATKIN, and the ARCHBISHOP OF CANTERBURY supported the Bill. Lord ARNOLD suggested that consideration should be given to the extension of the Bill to cover cases of mental disturbance due to distress and despair arising from solicitude for the child or extreme poverty, or either of these.

The EARL OF MUNSTER said that everyone would sympathize with the object of the Bill in so far as it was intended to reduce the number of cases in which sentence of death had to be pronounced by the court on a woman who had killed her child in distressing circumstances, and for whom it was clear that a reprieve would be granted. The proposal in the Bill was to get rid of the limitation under the Act of 1922 to cases where the child was "newly born," and to substitute a limitation to cases where the child was not more than 12 months old. The term "newly born" had been criticized on the ground that it was somewhat indefinite, but experience did not suggest that the difficulty would, in fact, be felt. In cases where a verdict of infanticide was returned the death of the child generally occurred within the first few hours of birth. He was advised that the courts had had no difficulty whatever in interpreting the term. The question for how long a period childbirth might be liable to have a disturbing effect on the mother's balance of mind was a medical one. In exceptional cases it might be a very long time, with possibly lasting effects on the mental balance. In considering these cases, however, it was necessary to have regard to what was normal. The Bill would not enable verdicts of infanticide to be substituted for verdicts of murder in any considerable number of cases. Nevertheless the Government would not oppose the second reading, and would be prepared to give it most careful consideration in committee.

Lord DAWSON said that when this question was first brought up after a painful case at the Central Criminal Court he did not go into the matter in his personal capacity, but took care, as President of the Royal College of Physicians, to refer it to a committee of experts. They went into the matter, and the conclusions which he had put forward in the debate were a result of that united wisdom. When their report was in his hands he brought it to a gathering of leading K.C.s and some medical men, and there was agreement such as he had indicated. Infanticide, happily, was not a common thing. The Bill dealt with quality rather than quantity. A number of his distinguished colleagues had assured him that the cases of insanity which were delayed and occurred during lactation were far more numerous than he had imagined.

The Bill was read a second time.

Doctor's Obstruction of the Highway

Sir CHARLES EDWARDS asked, on March 11, whether the Home Secretary knew that a medical practitioner of Peckham was summoned for leaving his car outside a house for fifteen minutes when visiting a patient, and was fined 10s. at the Old Street police court on February 25; Sir Charles, in order that doctors could carry on their professional duties, asked the

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

244 Familial Syphilis and Tuberculosis

RÖSSLE (*Schweiz. med. Wschr.*, January 1, 1938, p. 3) discusses the occurrence of syphilis and tuberculosis in families. As a pathologist, his series is necessarily smaller than that of a clinician. Morphological changes in the disease, geographical differences in distribution, and an increase of late manifestations of syphilis tend to confuse the issue, but he was able to show that syphilis does not attack the same organs in the same family and that its forms are becoming less numerous, the disease tending to become more localized in a few organs. The investigation of the occurrence of tuberculosis in families showed that the disease does not appear or develop with any marked similarity in members of the same family. Post-mortem examinations of married couples brought evidence of the relatively high immunity to tuberculosis in adults. The same is not true of children, but whether this is due to age or to hereditary disposition remains an open question. The author is of the opinion that the existence of a specific disposition to tuberculosis is by no means proven. The dangers of exogenous infection in families have not been efficiently overcome yet, and until they are, the possibility of a "tuberculous disposition" cannot be accepted as a factor in the production of tuberculosis.

245 Liver Diet in Diabetes

L. PINELLI (*Rass. Clin. Terap.*, November-December, 1937, p. 334) records his investigations on the effect of a liver diet in diabetes. According to him only 30 to 40 per cent. of diabetics show any pancreatic lesion, though there may be extensive lesions in the pancreas without diabetes. On the other hand, the liver is often affected in diabetics, and some authors have gone so far as to speak of actual "hepatic diabetes"; others have described a hypoglycaemia following the administration of liver or liver extracts. Pinelli gives details, with comparative blood-sugar curves before and after treatment by liver and other diets, of sixteen cases of diabetes, which he divides into severe, moderate, and mild types; two normal individuals acted as controls. He concludes that: (1) in normal individuals and mild diabetics a liver diet tends to produce hypoglycaemia, though not to a very marked extent; (2) in moderate diabetes there is a delayed response with some degree of hypoglycaemia; (3) in severe diabetes there is a definite hyperglycaemia.

246 Encephalomyelitis following Rubeola

L. HALLÉN (*Nord. med. Tidskr.*, January 8, 1938, p. 54) gives an account of three cases of encephalomyelitis observed during an extensive epidemic of rubeola which broke out in the spring of 1937 in Uppsala. The ages of the patients were 13, 15, and 13, and in all three cases there was a history of measles at an earlier date. The intervals between the appearance of the rubeola rash and the fulminating onset of signs of encephalomyelitis were four, five, and two days respectively. Headache, fever, loss of consciousness, convulsions, cervical rigidity, and certain abnormalities of the reflexes were among the salient features indicative of encephalomyelitis. The complete recovery recorded in the first two cases and the great improvement in the third case, which is still under observation, were effected in a comparatively short time. The author's survey of fourteen similar cases he has discovered in the literature shows how closely they resembled each other. The recovery rate is so high that in only one case has it been possible to conduct a post-mortem examination. The interval between the appearance of the rash and that of signs of encephalomyelitis

ranged within the narrow limits of one and six days, and was in most cases only three to four days. In eight cases the encephalomyelitis was heralded by headache and vomiting. As many as nine of the patients were under the age of 15, and all were under the age of 33. There would seem to be no sex preference.

Surgery

247 Haematuria in Appendicitis

D. C. COLLINS (*Urol. cutan. Rev.*, January, 1938, p. 22) states that haematuria accompanies appendicitis more often than is generally supposed. In 1,402 unselected consecutive cases of acute appendicitis at the surgical department of the College of Evangelists, Los Angeles, haematuria was found in 124 (8.84 per cent.). The presence of haematuria caused an average pre-operative delay of four hours before primary genito-urinary disease could be excluded, with the result that the mortality in this group was 6.2 per cent., as compared with 4.7 per cent. for the whole series. About 84 per cent. of the cases of haematuria were associated with a fixed retrocaecal appendix. The haematuria disappeared usually on the fourth day after operation, the extremes varying from the first to the twenty-second day.

248 Nephrolithiasis

J. SCHMIDT (*Münch. med. Wschr.*, January 14, 1938, p. 51), who practises in a small town in Yugoslavia, since 1919 has seen thirty-two patients suffering from nephrolithiasis among a population of 2,000. He believes that the drinking-water is to some extent responsible for this high incidence of renal stone. The water comes from deep artesian wells, and contains a reddish sediment not unlike that found in the urine of the patients. Another predisposing factor was the diet, which is rich in meat and alcohol and poor in vegetables. In the majority of cases there were no complications, but in a few cases there supervened pyelitis, anuria, and uraemia.

249 Branchiogenic Fis'tula

M. SPITZY (*Zbl. Chir.*, January 15, 1938, p. 114) records the results of electrocoagulation in five cases of branchiogenic fistula. A preliminary cauterization of the fistulous track is indispensable, and always requires a general anaesthetic. The track is usually 11 to 14 cm. long, and its course can be investigated radiographically with the sonde *in situ*. An active electrode then takes the place of the sonde and a current of 0.7 to 0.8 ampere is passed while the electrode is being moved gently up and down. The resulting small wound at the opening of the canal usually heals within five weeks. There were no complications following this treatment in the five cases reviewed; it should not be attempted, however, after an unsuccessful operation.

Therapeutics

250 Staphylococcal Septicaemia

J. BERGER and R. WORMS (*Bull. Mém. Soc. méd. Hôp. Paris*, January 31, 1937, p. 141) record the case of a man who developed staphylococcal septicaemia as the result of a whitlow. There were foci in the lungs, in the epididymis, and possibly in the perirenal tissue. Four blood cultures showed the presence of staphylococci, which were also present in the fluid of a pleural effusion and in the urine. He was treated by Ramon's anatoxin, anti-staphylococcal serum, and disarticulation of the finger, and ultimately recovered. The infection reached

The Committee of the Athenaeum has elected Sir John Ledingham, F.R.S., under Rule II of the Club, which empowers the annual election of a certain number of persons of distinguished eminence in science, literature, the arts, or for their public services.

Mr. W. McAdam Eccles, M.S., F.R.C.S., has been appointed chairman of the United Kingdom Council of the International Hospital Association, a post vacant since Mr. H. L. Eason resigned on becoming Principal of the University of London.

King Edward's Hospital Fund for London has received a donation of £5,000 from the League of Mercy for distribution to the London hospitals. This is the fortieth contribution received from the League of Mercy since its foundation in 1899, and the amount of money it has provided for the London hospitals now totals more than £570,000.

Dr. Frederick Price has been elected a Corresponding Member of the Société Française de Cardiologie.

Hawaii has recently had the severest and most virulent epidemic of measles in its history. The number of reported cases from November, 1936, when it started, until September, 1937, when it ended, equalled the number reported during the preceding twenty years. The number of deaths from measles during the first three months of 1937 exceeded that for any cause except heart disease and pneumonia, and the respective rates per 100,000 of population were 102, 110, and 135.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111

The TELEGRAPHIC ADDRESSES are
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology*
Westcent, London.

SECRETARY, *Medisecra Westcent, London*.
The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh), and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin).

QUERIES AND ANSWERS

Cardiac Massage

The anaesthetists committee of the Glasgow Royal Infirmary would welcome information on instances of cardiac massage as a resuscitative measure for cardiac failure during anaesthesia. Descriptions of cases with special points of interest, or other references, may be sent to Dr. W. B. Primrose, at 10, Park Quadrant, Glasgow, C.3, or at the Infirmary.

Painful Heel

"D. C." writes: I have a patient, aged 76, whose only recreation is walking. For the past three months he has complained of pain under the os calcis; this comes on after walking for some time. The time interval is getting less, and now little exertion brings on pain. I have tried rubber pads, a raised heel, and massage without appreciable effect. X-ray examination shows "some minute points of calcification just below the os calcis; no definite bony spur." I should be glad of any advice as to treatment of this condition.

Income Tax

Allowable Expenses

"S. M." has, during the past year, (a) bought a share in a partnership, (b) bought and furnished a house, and (c) sold his old car and bought a new one. He asks what relief from income tax can be claimed in respect of these transactions.

** In respect of (a) and (b) none, for in both cases the expenditure represents an outlay of capital and consequently gives rise to no claim. As regards (c), if the old car had been used professionally we are of opinion that our correspondent can deduct as an expense the net cost of replacement, less any amount due to "improvement." For example, if an old car costing £200 has been sold for £50 and a new one purchased for £225, he can claim the net cost of renewal, £225 - £50 = £175 (the amount expended) less £25 (the improvement element)—that is, £150 net. We assume that he has not been allowed depreciation in respect of the car sold and does not intend to claim it on the new car.

LETTERS, NOTES, ETC.

Posture of Children

In these days when the need for physical fitness is being stressed by all and sundry, anything that helps to achieve this desirable end is to be welcomed. Not least among the matters conducive to physical fitness is the maintenance of a correct posture. The evils, for example, of any abnormal relation of one part of the axial skeleton to another are not limited to the deformed region, but extend from the top of the head to the soles of the feet. Once incorrect posture has been adopted as the result of faulty habits, bad health, fatigue, the wrong physical attitude tends to persist. It is therefore essential that those who have the care of children should do what they can to encourage the adoption of such a posture as will make for good health. To this end we welcome the twenty-three-page pamphlet entitled *Posture and Exercise for Young Children*, by Dr. John Gibbens, and published by the National Association of Maternity and Child Welfare Centres and for the Prevention of Infant Mortality. It can be obtained for 6d. on application to Carnegie House, 117, Piccadilly, W.1.

Dr. Nash's Cookery Book

Simpkin Marshall, Ltd., Stationers' Hall Court, E.C.4, inform us that they are receiving applications from medical officers of health for various boroughs and county councils for copies of *Dr. Nash's Cookery Book* for free distribution. Under the agreement of the Publishers' Association they are permitted to give a special discount to such councils providing the books are given away free. Medical officers of health can obtain from Messrs. Simpkin Marshall the terms they are prepared to grant for redistribution. A notice of the book appeared in our issue of December 11, 1937 (p. 1172).

Corrigendum

ROUSSEL LABORATORIES LTD. write: In the leading article in the *Journal* of March 5 (p. 552) it is stated that, "According to de Leon prontosil will cure malaria. . . ." May we point out that the preparation used by de Leon in the treatment of fifteen cases of malaria was Rubiazol Roussel, not prontosil or sulphanilamide. Rubiazol is an azo dye possessing a carboxylated function, and has the formula 6 carboxy- 2, 4 di-amino-4 sulphamide-azo-benzene. It differs from both prontosil and sulphanilamide.

Sulphanilamide is, we understand, the generic term applied to para-amino-benzene-sulphamide, which is a white body without any azoic molecule. Prontosil differs from rubiazol in that it does not carry the COOH group.

mates to that seen in the adult diabetic. White describes a large series of juvenile diabetics and their management with protamine insulin; some of the children did well with only one dose a day. From the data available the author concludes that protamine insulin has a more beneficial effect upon growth and development than ordinary insulin. Heights and weights of children treated by the two kinds of insulin are given and compared at intervals of a year. The undernourished child seems to do especially well on protamine insulin and grows and gains weight rapidly. Diabetic coma occurs less frequently with protamine insulin and dietary indiscretions have less harmful results. Sufficient time has not elapsed to allow of any opinion being formed as to the effect of protamine insulin upon the progress of the diabetes.

257 Bronchopneumonia in Infancy

J. SIEGL (*Wien. klin. Wschr.*, February 4, 1938, p. 141) states that in the first three years of life, while croupous pneumonia has in general a favourable prognosis, the mortality from bronchopneumonia is 30 to 50 per cent.; those forms are most dangerous which are accompanied by marked circulatory involvement or by anorexia, vomiting, and diarrhoea, or which complicate a pre-existing disturbance of nutrition. The prognosis of that form of bronchopneumonia in infancy which is associated with the formation of pulmonary abscesses, followed by pleural effusion or pyopneumothorax, is practically hopeless. Otitis media is often present, without materially affecting the prognosis. In treatment general nursing measures are specially important. The trunk should be somewhat raised and the head bent slightly backwards; the carrying of an infant—in the upright position in the mother's or nurse's arms—for short periods in the open air is helpful. Fresh-air treatment in recumbency, continuous in warm and intermittent in cold weather, is of therapeutic value. Sedatives are urgently called for when there is pronounced restlessness. Circulatory impairment should be treated by camphor, by adrenaline, or by caffeine (0.03 to 0.05 gramme in infants, 0.1 to 0.2 gramme in children, thrice daily) combined with sedatives. All these should be given orally if possible, except in acute circulatory failure. Incipient pulmonary oedema calls for venesection from the superior longitudinal sinus or ante-cubital vein, or—if the required amount (up to 60 c.cm. in an infant) cannot be thus obtained—for arteriotomy, the temporal being preferable to the radial artery. In the most serious cases, especially when the liver is much swollen, 20 to 40 c.cm. of 20 per cent. dextrose solution may be given intravenously; in severe collapse one or two applications of cold water (20° to 25° C.) may be made with the child immersed in a warm bath (37° C.). Meteorism should be treated by rectal intubation or irrigations, or by the injection of pituitrin. Serotherapy is less useful than repeated intramuscular injections of 10 to 20 c.cm. of adult blood; quinine is not advocated. The diet should in general be that appropriate to the age; compulsory feeding is to be deprecated.

258 Chronic Pancreatitis and Pyloric Stenosis

J. L. NICOD (*Schweiz. med. Wschr.*, January 29, 1938, p. 105) describes a condition of the pancreas the symptoms of which closely simulate those of hypertrophic pyloric stenosis. In one child symptoms appeared at 3 months, in another they were present at birth. Both cases terminated fatally. In both vomiting persisted in spite of treatment. The stools were frequent and soft, and showed an increase of fat over the normal. Pregnancy and the confinement were normal. In neither case was syphilis present. At necropsy the head of the pancreas was enlarged and thickened in both cases. In one the islets of Langerhans were atrophied; in the other they were normal. Microscopically chronic duodenitis and cystic pancreatitis were found to be present. Malforma-

tions and syphilis are the most common affections of the pancreas in the newborn. The aetiology of these two cases could not be ascertained. The author is of the opinion that chronic cystic pancreatitis is a definite clinical entity. It is a condition in which the pancreatic inflammation is primary, the duodenal secondary. The repeated and serious vomiting is the result of a mechanical factor—enlargement of the head of the pancreas—and an inflammatory factor—duodenitis.

259 Convalescent Serum in Scarlet Fever

M. FOX and M. HARDGROVE (*Arch. intern. Med.*, September, 1937, p. 494) record their observations on 1,028 cases of scarlet fever, of which 139 were treated with commercial antitoxin, 589 with human convalescent serum, and 300 received neither antitoxin nor immune serum. The sex and average age were approximately the same for all the groups. The doses of convalescent serum ranged from 10 to 100 c.cm., the average being 33.6 c.cm. in cases treated at home and 32.7 c.cm. in hospital patients. The incidence of reactions after convalescent serum was only 1 per cent., as compared with 35 per cent. after the use of commercial antitoxin. When the convalescent serum was given early in adequate doses there was an apparent decrease in the mortality rate as well as a reduction in the incidence of complications and in the length of time before a normal temperature was reached.

260 C. R. HYLAND and L. R. ANDERSON (*Amer. J. Dis. Child.*, September, 1937, p. 504) state that of 102 children exposed to scarlet fever and given convalescent serum in doses of 10 c.cm. for those under 10 years of age and of 20 c.cm. for those over 10, only four developed the disease, which was mild in three and moderately severe in one. In all four cases the incubation period was prolonged. Of forty-seven cases to which convalescent serum was given therapeutically all but one showed improvement. The writers came to the conclusion that the percentage incidence of complications, especially adenitis, otitis, and nephritis, increased with each day's delay in the therapeutic administration of serum.

261 Rickets Resistant to Vitamin D Therapy

F. ALBRIGHT, A. M. BUTLER, and E. BLOOMBERG (*Amer. J. Dis. Child.*, September, 1937, p. 529) record the case of a boy, aged 16, who had suffered from rickets since the age of 1 year in spite of treatment with vitamin D. Histological evidence demonstrated that the condition was true rickets, and the changes in the calcium and phosphorus metabolism were similar to those of infantile rickets. Evidence is also given that the cause of the disorder was not hyperparathyroidism. It was shown that the resistance to vitamin D was not due to failure to absorb the vitamin, and it was only when massive doses were given that the disorder of metabolism was corrected and healing of the rickets took place. Evidence is also presented which suggests the necessity for observing such patients carefully lest in healing the rickets too large doses of vitamin D produce hypervitaminosis. Cases of this type seem to be extremely resistant to the antirachitic vitamin, but this resistance can be broken down by massive doses. Ultra-violet irradiation was of no value in this case. This patient's condition is an example of a type of rickets of as yet unknown origin; six similar cases had been recognized at the Boston Children's Hospital.

262 Increase in Rickets

E. ROMINGER (*Med. Klinik*, January 7, 1938, p. 1) points out that recently there has been a marked increase in the number of cases of rickets reported not only in Germany but in all parts of the world, including some countries in which this disease was supposed to be practically unknown. Rickets has been observed both in

the blood through the veins rather than through the lymphatics. There was no lymphangitis or adenopathy. The digital veins showed endophlebitis and thrombosis extending well beyond the focus of suppuration. Numerous subcrepitanr rales were heard over various areas of the lungs, and abnormal shadows in several areas were shown by radiography. The left epididymis was greatly swollen. The pulmonary lesions subsided without suppurating and the epididymis recovered without operative interference. The serum used was that of the Pasteur Institute. In ten days 280 c.cm. of this serum was injected. Of the anatoxin, seven injections were given in amounts rising from 0.25 c.cm. to 2 c.cm. Three blood transfusions were administered, the third causing a violent reaction which seemed to produce an abrupt cessation of the pyrexia. The authors admit the difficulty of proving that the cure of the disease was due to specific therapy, but maintain that the gradual improvement coincided with the administration of the anatoxin and the serum, and claim that such treatment is helpful in the cure of this condition.

251 Carbon Dioxide Baths in Graves's Disease

A. VILKOMIRSKY and E. RESNITZKY (*Méd. soviétique*, 1937, 12, 30) have investigated the effect of carbon dioxide baths (Nauheim treatment) in patients suffering from Graves's disease. The effect of the treatment was unfavourable in practically every case.

252 Myasthenia Gravis

H. VERBIEST (*Nederl. Tijdschr. Geneesk.*, February 5, 1938, p. 622), who records five cases of myasthenia gravis in patients aged from 20 to 46, of whom four were women, discusses the part played by the ductless glands in the causation of the disease. The administration of suprarenal preparations was without effect, and oestradiol made the symptoms worse. In Verbiest's experience prostigmin causes only a temporary relief of a few hours' duration. Verbiest also observed some patients who became habituated to this drug. Prostigmin is of great value, however, when the symptoms are sufficiently severe to endanger life. In all other cases ephedrine is preferable and may give rise to permanent improvement.

Diseases of Children

253 Gierke's Disease

Under this name F. PARADISO (*Pediatrics*, Naples, January, 1938, p. 32) describes a disease of childhood characterized by retarded physical development, hepatic enlargement, and a disturbed carbohydrate metabolism, with an abnormally high hepatic glycogen content and a tendency to hypoglycaemia. Gierke's two cases, reported in 1929, concerned children aged 4 and 8 respectively; the diagnosis was made at necropsy, which showed the liver parenchyma and renal tubules to have a high glycogen content. Cases so far noted appear to number twenty-four, of which seventeen have been in males. In Paradiso's case, a mentally normal child showed from the age of 3 to 7 physical development corresponding to that of a child two years younger, with retarded carpal ossification; the liver was palpable well below the umbilicus, and the diagnosis was established by microscopic examination of a fragment of liver (removed at laparotomy), which showed perilobular and intercellular infiltration by cellular connective tissue, and an enormous excess of glycogen in the hexagonal cells. Other features present, and noted also in some other cases in the literature, were a plump, lunar facies, shortness of the limbs, obesity recalling that of dystrophia adiposo-genitalis, and diastasis of the coronary suture; cardiac enlargement, probably connected with a local accumulation of glycogen; muscular hypotonia; a constant hypoglycaemia

and ketonuria during fasting, occasional hypoglycaemic attacks, an irregularity of the blood-sugar curve after feeding tests or the administration of adrenaline, and hypersensitivity to insulin; and hypercholesterolaemia. Diminution of carbohydrate tolerance, glycosuria, jaundice, and splenomegaly were absent, and hepatic functional tests gave normal findings; Pettenkofer's test for bile-salts in the urine was positive, and a reduction of Fehling's solution by the concentrated, hydrolysed urinary residue suggested the presence of glycogen. Diagnosis at present would seem to be dependent on biopsy or necropsy, and is made more difficult by the occurrence of a similar syndrome in which the enlarged liver is infiltrated not by glycogen but by fatty substances. Prognosis is uncertain; the infants are very sensitive to intercurrent infections, but spontaneous cures have been recorded, as well as the development of diabetes mellitus. Cure was reported by Unshelm after treatment of the liver with x rays in a child aged three months.

254 Skin Tests in Whooping-cough

A. R. THOMPSON (*J. Hyg.*, Camb., January 1, 1938, p. 104) reviews the literature and records his observations with the intradermal test in 1,300 cases of whooping-cough. He was unable to support the claim that the intradermal response to Sauer's vaccine in the strength commonly employed (10,000 million organisms per c.cm.) was of value either in demonstrating immunity to whooping-cough or in the early diagnosis of the disease. The bacterial content of the vaccine appeared to be too high for skin-testing purposes, giving rise to inflammatory lesions of a non-specific character rather than to specific allergic reactions. The intradermal response to pertussis endotoxin, on the other hand, produced a reaction resembling that seen in the Dick and Schick tests. Similar reactions, however, could be elicited in the skin of about 30 per cent. of individuals with no history of the disease, but this might have been due to latent immunization. Thompson concludes that the pertussis endotoxin test is of some value in assessing the immune state of the individual, and also as a diagnostic reaction in early, atypical, or late whooping-cough.

255 Staphylococcal Bacteraemia

J. WU (*Chin. med. J.*, December, 1937, p. 807) records forty-three cases of staphylococcal bacteraemia in Chinese children admitted to the Peiping Union Medical College Hospital. The condition is most often found in young children and infants, and the mortality is very high. The infection could usually be traced to some sort of skin lesion in the summer, or to respiratory diseases in the winter. Premature infants and those rendered delicate by other conditions were specially susceptible. Skin infections resulting from abrasions, or from skin punctures for diagnostic or therapeutic purposes, may at times lead to bacteraemia, and two cases to illustrate this point are reported. Although specific therapy was not available, energetic treatment along general lines at times gave gratifying results. Prompt surgical treatment of all local conditions, such as empyema, osteomyelitis, and suppurative arthritis, is needed, together with repeated blood transfusions.

256 Protamine Insulin Treatment of Juvenile Diabetes

P. WHITE (*Sth. med. J.*, Le Grange, January, 1938, p. 15) states that the fundamental characteristics of juvenile diabetes, differentiating it from the adult type, are its severity, its rapid progression, and the development of complications. The W-shaped curve of the blood sugar in juvenile diabetes is also characteristic, and shows three high points and two low points when insulin is administered twice a day. When an injection of ordinary insulin is given in the morning and one of protamine insulin in the evening the W-shaped curve is flattened and approxi-

Vitamin Concentrate or Natural Food?

The normal daily dosage of Bemax, i.e., 1-ounce, provides 200 International units of Vitamin B₁, which is from four to ten times as much as the recommended daily dosage of certain Vitamin B₁ "concentrates" advertised to the medical profession. If a higher intake is required, it is possible to supply as much as 600 to 800 units of Vitamin B₁ daily by the administration of three to four tablespoonfuls of Bemax, and this in an entirely natural form at only a fraction of the cost of concentrates.

The Vitamin B₁ potency of Bemax is assured by biological assay of every day's output, and is from 12-15 International Units per gramme, about 400 units per ounce.

BEMAX

A unique natural source of accessory nutritional factors.

Sterility and Habitual Abortion

The increasing use of Vitamin E for habitual abortion and sterility of dietary origin demands a wheat germ oil of proven high activity and of stable Vitamin value. Such an oil is available for the medical profession in Fertitol.

FERTITOL

Wheat Germ Oil Capsules

A highly active source of Vitamin E.

BOAT RACE

We have space at the Bemax Factory, Wharf at Hammersmith Reach for about 400 members of the medical profession and friends to view the Oxford and Cambridge Boat Race to be held on April 2nd. Early application for tickets should be made to the address below.

Vitamins Ltd., The Bemax Laboratories (Dept. B.56), Upper Mall, London, W. 6.

OSTOMALT

IS NEEDED

Winter is past, but the effects of repeated catarrhal infections are still with many of us. Ostomalt, by making vitamin deficiencies good, and helping to replenish body stores of calcium and phosphorus, re-establishes tone and appetite and restores the normal mechanism of the organism.

Winter-weakened children may be strengthened by Ostomalt for impending operations postponed to warmer weather; adults may be invigorated for summer activity. One appetising teaspoonful three times a day is the usual dose (made sufficient by the triple concentration of vitamins A & D in Ostomalt).

Prices (except in Eire), 1 lb. jars, 1.9; 1 lb. jars, 3 - Dispensary jars (more than seven times as much as 1 lb. jar), 17. - subject to usual professional discount.

VITAMINS A and D MALT (vitamin B)

ORANGE JUICE (vitamin C) CALCIUM Glycerophos.

GLAXO LABORATORIES

EX. B.P. 3434

Lapland and in the Tropics, at high altitudes and in the plains, in countries where the sun is hardly seen for three months in the year and in Egypt. What is perhaps even more remarkable, it would seem to prevail even in those countries where breast-feeding is the universal rule. At first sight these facts would appear to negate the firmly established view that rickets is a deficiency disease largely due to improper feeding and lack of sunshine, and hence that breast-feeding is the best prophylactic against it. Rominger has shown, however, that other factors have to be considered. Thus in some countries where breast-feeding is the rule the mother's diet is grossly deficient in vitamins, while, on the other hand, in some tropical countries the children never have a chance of seeing the sun until they are old enough for rickets to have developed; for instance, in Nyasaland the inhabitants build their houses on piles, and the children are shut up in them until they are old enough to climb down the ladders by themselves. The author concludes that rickets is not a pure D avitaminosis, but, as Glisson wrote even in 1650, the result of a number of adverse factors, which are usually first brought to light by a deficiency in vitamin D or a lack of sunshine.

Obstetrics and Gynaecology

263 Squamous Epithelium in the Corpus Uteri

According to F. SIEGERT (*Arch. Gynäk.*, December 28, 1937, p. 135) the areas of squamous epithelium sometimes found in the endometrium are now known to be derived not from remnants of the Müllerian ducts but from the basal layer of the columnar epithelium of the adult—in all probability as a result of hormonal imbalance. It is only in combination with hyperplastic conditions of the myometrium, endometrium, or both that squamous epithelium is found—for example, in general glandulo-cystic endometrial disease, or when there is circumscribed glandular hyperplasia around a mucous polypus or myoma, or occasionally in uterine endometriosis. These are all conditions associated with excessive secretion of the ovarian hormones. As well as others, Grumbrecht in normal and Migliavacca in castrated rats have experimentally induced the formation in the endometrium of squamous epithelium by prolonged administration of follicular hormone. It may now be regarded as almost certain that in the human subject such endometrial metaplasia is due to excessive stimulation by folliculin. Clinical evidence pointing in this direction is scanty, for the findings usually come from curetting without an abdominal operation. Siegert records a case in point. A patient, aged 30, was treated for irregular bleeding by curetting of a glandulo-cystic endometrium and removal of a left parovarian cyst. Thirteen months later similar symptoms led to a second curetting of the hyperplastic endometrium, which contained a polyp showing adenocarcinomatous changes and islands of squamous epithelium, including cell nests. The right ovary was then found to be enlarged and was removed; it showed small cysts, fibromatous nodules, but no trace of a corpus luteum. Siegert leaves open the question of a connexion between excess of follicular secretion and the genesis of carcinoma of the body of the uterus; he does not doubt, however, that when squamous epithelium is found in a corpus uteri which is carcinomatous it is not a secondary but the precedent condition.

264 Peritonitis and Post-partum Menstruation

G. KAHLENBERG (*Zbl. Gynäk.*, January 29, 1938, p. 241) records the case of a primipara, aged 31, who four days after spontaneous delivery, in which only one vaginal examination had been made, was operated on for purulent peritonitis, abdominal drainage and intraperitoneal sero-

therapy being undertaken. An adnexal tumour which was not tender was palpable on discharge from hospital on the forty-second day. Five weeks later the occurrence of the first menstrual period was followed immediately by a second attack of peritonitis, which was treated like the first and was also caused by the *Staphylococcus albus*; cure followed. The adnexal tumour, although showing no gross changes at the second operation, was regarded as the source of the second peritoneal infection. The menstruation which followed, observed in hospital, was uneventful. Similar cases are said to be absent from the literature, although the onset of peritonitis during the menses is not altogether exceptional. Schneider in 1923 recorded a case of lethal peritonitis immediately following the second menstruation after a normal labour and puerperium.

Pathology

265 Leucocyte Count in the Pleurisy of Artificial Pneumothorax

H. HALLÄNDER (*Hygiea*, Stockh., December 31, 1937, p. 904) has during the past three years investigated the behaviour of the leucocytes in response to the induction of a pneumothorax, with special reference to the development of a pleural effusion. By means of the leucocyte count he hoped to ascertain early whether a pleural effusion in any given case was a trivial matter or a sign of extension of the disease within the lung. His material consisted of twenty-seven cases of artificial pneumothorax complicated by pleurisy, before the onset of which most of the patients had been afebrile. The pleurisy had begun within eight months of the induction of a pneumothorax. In every case blood counts had been undertaken from the time of the induction of the pneumothorax, and when the pleurisy was developing they were repeated daily or every other day, and later at intervals of a week or a fortnight. They were undertaken in the fasting state in the morning, and on each occasion 400 cells were counted. In sixteen of the twenty-seven cases the evolution of the pleural effusion was unassociated with any progress of the pulmonary disease, whereas in the remaining eleven cases there was an exacerbation or an extension of the pulmonary disease. Common to all the cases in which the disease progressed in the lungs was a displacement to the left of the Arneth count, and in only two cases had the count returned to normal on the patients' discharge. Checking up this feature of the blood count with the temperature chart, the rate of sedimentation of the erythrocytes, and the x-ray findings, the author considers that none of these three tests was as consistently reliable as the leucocyte count from a prognostic point of view, for in five of the eleven cases both the temperature and the sedimentation rate returned to the original figures, and in two cases the radiological evidence of progress of the disease came comparatively late.

266 Allergic Pulmonary Phenomena

H. E. MEYER (*Med. Welt*, December 25, 1937, p. 1808) reports eight cases of transitory pulmonary infiltration accompanied by an increase in the number of the eosinophils in the blood. With W. Löffler he believes that these infiltrations are in fact allergic phenomena produced by a number of substances, but mainly by the tubercle bacillus, although none of the cases developed later a tuberculous lesion. In a number of cases the allergic phenomena and the pulmonary infiltration were produced by pollen. The infiltration and the other allergic manifestations quickly subsided following the intravenous administration of calcium. The author believes that his cases belong to the category described by Engel of Shanghai under the name of "privet cough," and by American workers under the name of "laurel fever."

CRUNCHY FOODS AND THE HEALTH OF CHILDREN

The inclusion in every child's diet of a quantity of hard, dry food is regarded as essential by many practitioners. Such food compels thorough mastication ; the regular exercise this gives to the jaws is believed to assist their correct development, thus preventing many possible troubles to the teeth in later life.

The importance of instilling the habit of thorough mastication is further stressed because of its value to digestion, to which the practice of swallowing insufficiently chewed masses of food is considered extremely harmful.

Many physicians therefore recommend that growing children should eat crisp Ryvita with their meals. Free samples of Ryvita for distribution to patients will gladly be supplied on request.

Bakeries in Birmingham

the scientific contraceptive

MIL-SAN is a bland, non-injurious, spermicidal jelly independent of variable physiological conditions of moisture or temperature. Since there is nothing to melt, dissolve or foam, MIL-SAN is immediately effective.

The formula of MIL-SAN is based on biological principles in harmony with the natural chemical and bactericidal balance of the vagina. Its spermicidal efficiency is due to: (a) A low pH secured by the reinforcing action of several acids which ensures the immediate immobilization and death of spermatozoa, despite the buffering action of the seminal fluid; (b) A low surface tension which causes the jelly to spread rapidly and to penetrate the rugae of the vaginal and cervical mucous membrane; (c) A degree of viscosity which ensures that it shall adhere to the cervix and upper vaginal tract and fornices, forming a chemical barrier preventing the penetration of spermatozoa into the os uteri.

The method of applying the jelly is simple, hygienic, and proof against carelessness. Each application of 7 c.c. is contained in a specially

made strong glass tube sealed at one end with a cork, at the other by a hard wax plug. In use the cork is removed, a bulb fitted behind the wax plug, and the tube inserted. Compression of the bulb forces the wax plug down the tube and ejects the contents. The empty tube, which is thrown away, proves the application and ensures the quantity. There is nothing to fill, nothing to clean. Each application is hygienic and complete.

MIL-SAN does not deteriorate and is not affected by climatic conditions.

There are no contra-indications to the use of MIL-SAN with a dependable condom or a properly fitted occlusive pessary. It is only by such combined use that the consequences of misuse of one or other of the methods can be minimized and the maximum practicable security obtained. MIL-SAN is on the N.B.C.A. Approved List for use with a cap or condom.

Literature setting out the ingredients and full particulars, together with a box of specimen tubes for examination, are sent on request to members of the medical profession.

A typical example of the high nutritive values retained in Heinz Strained Foods. (Figures show percentages on the wet basis)

Vegetable and fruit purées, rich in mineral salts, vitamins and other soluble nutriment, constitute the perfect diet for infants and cases of nutritional anaemia.

But despite the wide approval shown by physicians, and a growing appreciation of this dietary by mothers, progress has hitherto been slow, owing to the practical difficulties encountered in home preparation.

The use of vegetables not truly fresh, mechanical losses through oxidation when boiling, and inefficient sieving out of the harsh fibres, inevitably impair the quality of the home-produced preparation.

Now, with the marketing of a range of strained foods by H. J. Heinz Co. Ltd., vegetable and fruit purées containing all necessary dietetic values are available in convenient bulk and form.

Heinz Strained Foods are prepared with all the advantages of the best factory method. The vegetables are specially grown in those areas where soil and climate combine to produce the best; they are harvested when they are just right, and cooked within a few hours of being garnered.

First, the ingredients are scrupulously cleaned. Cooking by light steam pressure in vacuum containers follows, leaving the contents perfectly disposed for comminution by extrusion, and at the same time ensuring retention of the essential juices and mineral constituents. Fine sieving having removed all fibres of a harsh or irritant nature, the purée is then adjusted to an acceptable consistency and sealed in vacuo, the sealed containers being immediately subjected to sterilization under constant conditions of time and temperature.

The purées thus offered are uniform, convenient and of the highest possible nutritive content.

NOTE: *Glass containers are not used owing to the deleterious effect of light on the value and palatability of the purées*

"CURTIS" R.T.M.

ABDOMINAL SUPPORT NO.1

for Steady, Permanent Support

The Curtis Model No. 1 Support has many advantages over the old type abdominal belt. It is light in weight and is scientifically designed to give maximum support upwards and backwards to the lower abdomen with minimum constriction. The hips are given complete freedom of movement and the support itself is extremely comfortable. Leading London Hospitals and the medical profession unhesitatingly prescribe Curtis Model No. 1—the most efficient support obtainable.

Modern Iron Therapy

Iron 'Jelloids' are an elegant and reliable means of administering the protocarbonate of iron. The preparation has none of the disadvantages of Pil. Blaud. The iron content remains fresh and unoxidized indefinitely, and

injury to teeth is avoided.

The 'Jelloids' are highly effective in the treatment of achlorhydric anaemia and indeed in all the simple anaemias in which massive iron therapy is indicated.

Iron Jelloids

You are cordially invited to apply for samples for clinical test.

PRICE - 4/6 per 4 oz. bottle.
Sample and Literature on request.

Serenol is a sedative with action on the centres of the nervous vegetative system, sympathetic and parasympathetic, and on the cortical centres. Recent knowledge has shown the interaction of nervous vegetative system and endocrine system, and on this knowledge SERENOL is based. It is thus a biological, not a symptomatic, sedative, and, unlike many other sedatives, has not a direct depressant action on the cortical cerebral centres.

Serenol is indicated in conditions of anxiety and general irritability, insomnia, hyperthyroidism, hyperadrenalism (as in neurocirculatory asthenia, effort syndrome), the so-called nervous palpitations of the heart, etc.

Serenol is given in the following dosage. For mild cases one to two dessertspoonsful on retiring. For more severe cases one dessertspoonful at 10 a.m., one dessertspoonful at 4 p.m. and two dessertspoonsful on retiring.

Serenol, being a biological sedative containing no barbiturate, is not habit forming.

**How We Assist in the
Purchase of Medical Practices**

Scotland's Oldest Insurance Company is prepared to assist Doctors in the buying of Medical Practices or Partnerships. The purchase price is repayable over a term of years, and a Life Assurance Policy is taken out as a collateral security. This scheme makes it unnecessary for a Doctor to approach his friends to act as guarantors, and enables him to pay for his practice out of income. After the repayment of the loan, the Life Policy becomes a valuable asset to the Doctor.

Many Doctors have already established themselves in practice with the aid of the "Caledonian" Scheme. The Interest Rates are particularly moderate. The Accountant's charges for investigating the practice and the Legal Fees for preparation of the deeds and documents in connection with the Loan are paid by the Company in completed cases. Arrangements can be made to meet special cases.

Full particulars on application to the Head Office,
or to any of the Company's Branch Offices.

**The problem of
SURGICAL STOCKINGS**

Doctors who prescribe Compri-Vena Stockings are sure that the most beneficial support is given as each one is made to the patient's measurements and needs. They have long been recommended for Varicosity and in conjunction with Injection Treatment as well as during and after Pregnancy. They are also invaluable in relieving undue leg strain. Compri-Vena Stockings are rubberless and yet elastic, are washable, cool in wear and invisible under ordinary silk stockings. They give real relief and preserve the shape of the legs. A skilled staff carefully follow all doctors' instructions. Full details from:

ELIMINATION ALKALINIZATION

More and more doctors are prescribing Salvitae to correct faulty elimination and toxic retention. Salvitae combats acidosis and restores the alkalescence of the circulating fluid.

SALVITAE

SALVITAE stimulates and encourages the natural activity of the several eliminative organs with the object of dispersing and excreting the toxic elements formed through dietetic errors and imperfect metabolism.

Professional samples and literature gladly sent on request.

THE RESIDENTIAL TREATMENT OF ALCOHOLIC & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address) — **WOODBIDGE, SUFFOLK**

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

RENDLESHAM HALL—SOUTH VIEW

Rendlesham Hall has 45 bedrooms and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated booklet giving particulars as to terms, etc., can be had on application to the

RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: WICKHAM MARKET 16. (Toll Call from London.)

Proprietors: The Norwood Sanatorium, Limited.

RUTHIN CASTLE, NORTH WALES

A Private Hospital or Clinic for the diagnosis and treatment of Internal Diseases (except Mental or Infectious Diseases). The Clinic is provided with a full staff of doctors, bacteriologists, chemists, radiologists, dietists, nurses, masseurs, and masseuses.

The surroundings are beautiful. The climate is mild. There is central heating throughout. The annual rainfall is 30.5 inches, that is, less than the average for England.

The inclusive weekly fees are from 15 guineas a week, according to the room occupied; rooms with bathroom are from 21 guineas. The charges include all chemical, bacteriological, X-ray or other examination advised by the doctors, and all the usual forms of treatment, in addition to board and lodging. There are no extra charges except for alcohol (when ordered) and laundry. An examination and consultation fee of 15 guineas is charged on the first visit.

Address: The SECRETARY, Ruthin Castle, North Wales.

Telegrams: Castle, Ruthin. Telephone: Ruthin 66.

CAMBERWELL HOUSE, 33, Peckham Road, London, S.E.5.

ST. ANDREW'S HOSPITAL FOR MENTAL DISORDERS NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients and certified patients of both sexes, are received for treatment. Careful clinical, biochemical bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton) who can be seen in London by appointment.

held in May next:

1. BUCKNILL SCHOLARSHIP, value 160 Guineas.
2. and 3. TWO EXHIBITIONS, value 55 Guineas
each.

Intending candidates should apply to the under-
signed for particulars and entry forms as early as
possible: the entry forms must be returned not later
than April 22nd, 1938.

C. O. G. DOUIE, Secretary,
University College, London (Gower Street, W.C.1).

UNIVERSITY OF OXFORD LORD NUFFIELD'S BENEFACTION FOR THE ADVANCEMENT OF MEDICINE

FIRST ASSISTANT IN THE DEPARTMENT OF CLINICAL MEDICINE

Applications are invited for the whole-time post
of First Assistant in the Department of Clinical
Medicine.

The successful candidate will be required to
assist the Nuffield Professor of Clinical Medicine
in the wards and outpatient department at the
Radcliffe Infirmary and to carry out research work
in the Department of Clinical Medicine. The
appointment is for two years in the first instance,
but will be renewable thereafter annually for not
more than three further years. The initial salary
is £650 a year.

Candidates, who must hold a medical qualifica-
tion recognizable in Great Britain, are requested to
send ten copies of their applications and of not
more than three recent testimonials to the Secretary
of Faculties, University Remedy, Oxford, so as to
reach him not later than Saturday, April 16th, 1938.

BRITISH POSTGRADUATE MEDICAL SCHOOL

DEPARTMENT OF PATHOLOGY.

A LABORATORY COURSE ON CHEMICAL
PATHOLOGY, conducted by Dr. EVEL J. KING,
M.A., Ph.D., will commence on April 15th, 1938.
The Course is whole-time and will last for six
weeks. Fee £9 9s.

This Course is part of the Course for the Diploma
in Clinical Pathology and only a limited number of
students can be accepted.

Early application for enrolment should be made to:
The Dean, British Postgraduate Medical School,
Ducane Road, London, W.12.

BRITISH POSTGRADUATE MEDICAL SCHOOL

Applications are invited for the post of HOUSE
SURGEON, to commence duty on April 1st, 1938.
Salary at the rate of £105 per annum, with board,
residence and laundry.
Applicants should have held previous House
appointments.

Applications, with copies of testimonials, should
be sent as soon as possible to the Dean, British
Postgraduate Medical School, Ducane Road,
Shepherd's Bush, London, W.12.

CITY OF PLYMOUTH MEDICAL OFFICER OF HEALTH'S DEPARTMENT.

THE CITY ISOLATION HOSPITAL.

ASSISTANT RESIDENT MEDICAL OFFICER

Applications are invited from registered medical
practitioners (unmarried, male) for the above
appointment, which is for a period of twelve
months, terminable by one month's notice on either
side.

The salary will be at the rate of £340 per annum,
with full residential emoluments, and any fees
received by the officer must be refunded to the
Council.

The successful candidate will be required to
work under the direction of the Medical Super-
intendent and will devote the whole of his time
to local duties, which will consist mainly of work
in the hospital and assisting at certain venereal
disease clinics. In addition to the above he will
be required to perform any other duties allotted
to him from time to time by the Medical Officer of
Health.

Applications, stating age, qualifications and ex-
perience, together with copies of not more than
three recent testimonials, must reach the undersigned
not later than Tuesday, April 12th, 1938.

Town Hall T. PEIRSON,
Stonehouse, Plymouth. Medical Officer of Health.

CITY OF NOTTINGHAM.

ASSISTANT MEDICAL OFFICER FOR MATER- NITY AND CHILD WELFARE WORK.

Applications are invited for the above post from
women medical graduates experienced in practical
midwifery and ante-natal and infant welfare work.
The duties will be chiefly in the ante-natal and
infant welfare clinics under the administrative
control of the Medical Officer of Health.

Salary £250, rising by annual increments of £25
to £370. The salary is subject to deduction under
the Superannuation Scheme of the Corporation.
The successful candidate will be required to submit
to a medical examination and to reside within the
City of Nottingham.

The appointment will be subject to one month's
notice on either side.

Application forms may be obtained from the
undersigned, and must be returned to me not later
than April 14th, 1938. Candidates will be a
disqualification.

Gouldhall, J. E. RICHARDS,
Nottingham. Town Clerk
March 15th, 1938.

CITY OF LIVERPOOL

CITY BACTERIOLOGIST'S DEPARTMENT

Applications are invited for a TEMPORARY
JUNIOR ASSISTANT BACTERIOLOGIST in the
above department. The appointment will be for
one year. Candidates will be required to possess a
reasonable medical qualification and evidence of
special bacteriological training is desirable. The
salary will be at the rate of £200 per annum. The
person appointed will be required to devote the
whole of his time to the work of the department.

Applications accompanied by copies of three
recent testimonials, together with details of training,
experience and research work, should be addressed to
The Town Clerk, Manchester Building, Duke
Street, Liverpool, 2, enclosed Temporary Junior
Bacteriologist, and be delivered not later than
April 9th, 1938.

Canvassing of members of the City Council will
be regarded as a disqualification.
W. H. BAILES,
March 21st, 1938. Town Clerk

Preliminary Examinations

The COLLEGE OF PRECEPTORS holds Preliminary Examinations for Medical and Dental Students in London and at Provincial Centres in March, June, September, and December. For Regulations, apply to the Secretary, College of Preceptors, Bloomsbury Square, London, W.C.1.

ROYAL ARMY MEDICAL CORPS

Applications are invited from medical men for appointment to commissions in the Royal Army Medical Corps.

Candidates will, for the present, be selected for commissions without competitive examination, and will be required to present themselves in London for physical examination and interview on, or about, 22nd April, 1938. They must be registered under the Medical Acts, and normally must not be over the age of 28 years.

Successful candidates will, in the first instance, be given short service commissions for five years. During the 4th year of this period they will be given the opportunity of applying for permanent commissions in either the Royal Army Medical Corps or the Indian Medical Service. Those not selected will retire on completion of five years' service with a gratuity of £1,000.

Candidates who are successful will, unless they are seconded to complete a hospital appointment, assemble at the Royal Army Medical College, London, on 2nd May, 1938.

Particulars of the Conditions of Service in the Royal Army Medical Corps, pay and allowances, and forms of application, may be obtained on application, either in writing, or personally, to the Assistant Director General, Army Medical Services, The War Office, London, S.W. 1.

ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in July, 1938.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty.

At the end of three years' service, officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Full opportunities exist for transfer to the permanent list, and periods of unemployed or half pay are very rare. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances.

Opportunities are available for officers on the permanent list for post-graduate study, to specialise, to take higher examinations and to obtain further qualifications.

Copies of the regulations for entry and conditions of Service, including rates of pay, allowances and retired pay may be obtained from the Medical Director-General of the Navy, Admiralty, S.W. 1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than 31st May, 1938.

COUNTY BOROUGH OF BLACKBURN. LADY ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from duly registered women practitioners for the appointment of Assistant Medical Officer of Health and Assistant School Medical Officer to act under the direction and supervision of the Medical Officer of Health who is also School Medical Officer.

The maximum salary will be £700 per annum. The commencing salary will not be less than £600 per annum, and will be fixed according to the qualifications and experience of the successful applicant, and will rise by annual increments of £25 to the maximum of £700.

The person appointed must have had at least three years' postgraduate experience in the practice of her profession and special experience of midwifery and ante-natal work. Special postgraduate experience in the treatment of venereal diseases and of diseases of children, and the possession of a registrable degree or diploma in Public Health will be deemed additional qualifications.

Applications to be made on forms to be obtained from the Medical Officer of Health, Victoria Street, Blackburn, and returned to him not later than Wednesday, March 30th, 1938, endorsed "Assistant Medical Officer of Health."

Canvassing, directly or indirectly, will be a disqualification.
Town Hall, Blackburn, Chas. S. Robinson, Town Clerk.
March 7th, 1938.

COUNTY BOROUGH OF BOLTON. RESIDENT ASSISTANT MEDICAL OFFICER. BOROUGH ISOLATION HOSPITAL.

Applications are invited from duly qualified medical men for the position of RESIDENT ASSISTANT MEDICAL OFFICER.

Candidates must have held resident hospital appointments and have had experience in the treatment of infectious diseases. The duties will include the medical care of patients in the Isolation Hospital and assisting the Male Venereal Diseases Officer in his work.

The person appointed will be required to reside at the Isolation Hospital. The salary will be £450 per annum, together with board and residence, valued at £150 per annum. Married quarters are not available. The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the selected candidate passing a medical examination.

Forms of application, with particulars of the duties, may be obtained from the Medical Officer of Health, Howell Croft North, Bolton, and completed applications, with copies of three recent testimonials, should be sent to the undersigned not later than April 5th, 1938. Canvassing, either directly or indirectly, will be a disqualification.

HAROLD B. ASHFORD, Town Clerk.
Town Hall, Bolton, March 19th, 1938.

CITY OF SHEFFIELD. CITY GENERAL HOSPITAL. ASSISTANT MEDICAL OFFICER.

Applications are invited from duly qualified medical men for the appointment of ASSISTANT MEDICAL OFFICER, Grade 2, at the above Hospital.

The Medical Officer appointed will be required to take duty in the Medical, Surgical or Maternity Departments as directed by the Medical Superintendent.

The appointment will be for one year only, and the salary offered is £300 per annum, with the usual residential allowances.

Previous hospital experience desirable. Applications, stating age, qualifications and experience, and accompanied by not more than three testimonials of recent date, should be sent to the Medical Superintendent, City General Hospital, Sheffield, 5, as soon as possible.

CITY OF NORWICH ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER, etc.

Applications are invited for the post of Assistant Medical Officer of Health and Assistant School Medical Officer with residence at the Isolation Hospital. Salary £600 per annum (including emoluments, valued at £150 per annum), rising by annual increments of £25 to £700 per annum. Board allowance at the rate of £60 per annum granted when absent from hospital on leave. The post is designated under the Local Government and Other Officers' Superannuation Act, 1922. For particulars apply to the Medical Officer of Health, 63, St. Giles Street, Norwich, by whom applications for the post must be received not later than April 11th.

COUNTY COUNCIL OF MIDDLESEX. VISITING ANAESTHETIST.

Applications are invited for the appointment of Visiting Anaesthetist at the COUNTY SANATORIUM, HAREFIELD. Candidates must be medical practitioners devoting the whole or the major part of their time to anaesthetics and must be specially skilled in the administration of anaesthetics by modern methods to patients undergoing thoracic operations.

The officer appointed will be required to attend one session per week, at a fee of £3 3s. 0d. per session. The appointment, which does not carry any superannuation rights, will be held during the pleasure of the Council and is terminable by one month's notice on either side.

Applications, stating age, qualifications and experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than April 9th, 1938. Relationship to any member or officer of the Council must be disclosed in the application. Application forms are not provided. Envelopes must be endorsed "Visiting Anaesthetist, Harefield."

Canvassing, directly or indirectly, will be a disqualification.

C. W. RADCLIFFE, "Z," Clerk of the County Council.
Middlesex Guildhall,
Westminster, S.W.1.
March 17th, 1938.

DERBYSHIRE COUNTY COUNCIL. WOMAN ASSISTANT MATERNITY AND CHILD WELFARE MEDICAL OFFICER.

The Derbyshire County Council require the services of a fully qualified whole-time woman Assistant Maternity and Child Welfare Medical Officer, experienced in Ante-Natal work, Midwifery and Children's Diseases, to hold under the direction of the County Medical Officer of Health consultations at the Ante-Natal and Maternity and Child Welfare Centres of the Derbyshire County Council and (under the like direction) to perform such other duties as appertain to the office.

The salary will be £600 per annum, rising by £25 per annum to £700 per annum.

The appointment will be a designated post under the Local Government and Other Officers' Superannuation Act, and the successful candidate will be required to pass a medical examination.

Forms of application may be obtained from the undersigned, to whom they must be returned, together with copies of not more than three recent testimonials, not later than April 4th, 1938.

W. M. ASH, County Medical Officer of Health.
New County Offices,
St. Mary's Gate, Derby.
March 10th, 1938.

PORTSMOUTH EDUCATION COMMITTEE. SCHOOL MEDICAL SERVICE.

The Committee invite applications from fully qualified candidates for the appointment of a male ASSISTANT MEDICAL OFFICER OF HEALTH and ASSISTANT SCHOOL MEDICAL OFFICER.

Salary £500-£25-£700 per annum. Experience in Refraction, Orthopaedics, Mental Deficiency, Diseases of the Ear, Nose and Throat, or any other branch of the work will be deemed a recommendation. D.P.H. an advantage.

The selected candidate will be required to pass a medical examination and contribute to the Council's Superannuation Scheme.

Forms of application obtainable from the Chief Clerk, Education Offices, Guildhall, Portsmouth, and should be returned not later than the first post on April 6th, 1938, to the undersigned. Canvassing in any form will disqualify.

Guildhall, F. J. SPARKS, Town Clerk and Clerk to the Education Committee.
Portsmouth, March 17th, 1938.

COUNTY BOROUGH OF HUDDERSFIELD. APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from registered Medical Practitioners (ladies) who have had special experience in ante-natal work and in the care of infants. Salary £500-£25-£700, initial salary according to experience.

The post will be designated under the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination before being appointed to the position.

Applications, stating age, full particulars regarding training, qualifications, and appointments held since qualification, should be forwarded to the Medical Officer of Health, Public Health Department, Huddersfield, along with copies of two recent testimonials, so as to reach him not later than Friday, April 1st, 1938.

Town Hall, SAMUEL PROCTER, Town Clerk.
Huddersfield, March, 1938.

LANCASHIRE COUNTY COUNCIL. PUBLIC ASSISTANCE COMMITTEE.

LAKE HOSPITAL AND DARNTON HOUSE INSTITUTION,
Ashton-under-Lyne, near Manchester.

(1) APPOINTMENT OF SENIOR RESIDENT MEDICAL OFFICER.

Salary £250 per annum, together with the usual residential emoluments. The person appointed will be required to take up duty on June 1st, 1938.

(2) APPOINTMENT OF JUNIOR RESIDENT MEDICAL OFFICER.

Salary £225 per annum, together with the usual residential emoluments. The person appointed will be required to take up duty on May 2nd, 1938.

Applications are invited from Registered Medical Practitioners for the above appointments at the Lake Hospital and Darnton House Institution, Ashton-under-Lyne, comprising 300 and 525 beds respectively.

The Hospital is recognised as a complete Training-School for Nurses.

Candidates must be unmarried. Preference will be given to candidates having previous hospital experience, especially in midwifery, and in the administration of anaesthetics.

The appointments will, in the first instance, be for a period of six months, the successful candidates being eligible for reappointment for a further period of six months at the end of that period.

Forms of application may be obtained from the County Medical Officer of Health, Public Assistance (Hospital and Medical) Department, County Offices, Preston, to whom all applications, accompanied by copies of not more than two recent testimonials, must be forwarded not later than Friday, April 1st, 1938.

GEORGE ETHERTON, Clerk of the County Council.
County Offices, Preston.
March 14th, 1938.

LANCASHIRE COUNTY COUNCIL. BIDDULPH GRANGE ORTHOPAEDIC HOSPITAL.

Applications are invited from duly qualified and registered medical practitioners for the post of ASSISTANT VISITING ORTHOPAEDIC SURGEON at the above Hospital, which contains 88 beds. Salary is at the rate of £250 per annum.

Candidates must have had special training and experience in orthopaedic surgery, and must possess the diploma of F.R.C.S. (Eng.). The successful candidate will be required to visit the hospital twice weekly. The appointment will be for a period of three years, terminable by one calendar month's notice on either side.

Applications, with copies of two recent testimonials, should be sent not later than April 2nd, 1938, to Dr. F. Hall, School Medical and Child Welfare Department, County Offices, Preston.
GEORGE ETHERTON, Clerk of the County Council.

SALOP COUNTY COUNCIL. Medical Inspection of School Children and Maternity and Child Welfare Schemes ASSISTANT MEDICAL OFFICER.

Applications are invited from registered medical practitioners for the post of ASSISTANT MEDICAL OFFICER to work under the above Schemes, at a commencing salary, according to experience—scale £500 per annum, rising by annual increments of £25 to a maximum of £700 (with travelling and out-of-pocket expenses), subject to a deduction of 5 per cent. for superannuation under the Local Government and Other Officers' Superannuation Act, 1922. The successful candidate will be required to pass a medical examination.

Preference will be given to candidates with a Public Health qualification, and experience in refraction work is desirable.

Applications, accompanied by a copy of three recent testimonials, should be received not later than April 13th, 1938, by the County Medical Officer, County Health Offices, Shrewsbury, from whom the necessary forms and conditions of service can be obtained.

W. L. EDGE, Clerk of the Council.
Shirehall, Shrewsbury, March 14th, 1938.

CITY AND ROYAL BURGH OF EDINBURGH. PUBLIC HEALTH DEPARTMENT.

The Committee of Management invite applications for the positions of two **HOUSE PHYSICIANS** and one **HOUSE SURGEON**, which will become vacant on April 30th.

Applicants must be fully qualified and registered. The appointments are for six months with board, residence, and washing provided. Salary at the rate of £100 per annum in each case. Applications, with copies of testimonials, stating age, to be forwarded on or before Thursday, April 7th. By order,

THOMAS CLAPHAM,

Secretary.

WORCESTERSHIRE COUNTY COUNCIL.

ASSISTANT COUNTY MEDICAL OFFICER.

Applications are invited from registered Medical Practitioners for the post of Assistant County Medical Officer, whose duties will include those connected with the School Medical Service and Maternity and Child Welfare, together with any other health duties the Council may require.

Applicants must be between the ages of 25 and 45, and preference will be given to candidates possessing the D.P.H. and with experience in the administration of dental anaesthetics.

The officer appointed will work under the supervision of the County Medical Officer, and will be required to reside in the district assigned to him by the County Council, and to devote the whole of his time to the work.

The salary will be at the rate of £500 per annum, rising by annual increments of £25 to £700 per annum, with an allowance of £60 per annum for the use of the officer's own motor car.

The post is designated under the Local Government and Other Officers' Superannuation Act, 1922, and the successful applicant will be required to pass a medical examination.

The engagement will be subject to three months' notice on either side.

Applications (on forms to be obtained from the County Medical Officer, County Buildings, Worcester) accompanied by not more than three recent testimonials, must be received by 12 noon on Wednesday, April 20th, 1938, addressed to the County Medical Officer, County Buildings, Worcester.

Canvassing disqualifies, and neither the names of the members of the County Council, nor of the Committee, will be supplied.

(Signed) C. H. BIRD,
Clerk of the County Council.

Shirrell, Worcester.

March 26th, 1938 [K.216.]

HOLLAND (LINCS.) COUNTY COUNCIL.

ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified and registered medical practitioners holding the Diploma in Public Health or an equivalent qualification, for the post of Assistant Medical Officer of Health (male). Candidates must not exceed 40 years of age.

The person appointed, who must have had postgraduate experience in radiology and in the diagnosis and treatment of tuberculosis, will be required to carry out all the duties assigned to him by the County Medical Officer, under whose direction and supervision he will act. He will not be allowed to engage in private practice.

The salary will be £600 per annum, rising by increments of £25 per annum to £750, together with travelling expenses according to the Council's scale.

The appointment will be a designated post under the Local Government and other Officers' Superannuation Act, and the successful candidate will be required to pass a medical examination.

The appointment will be determinable by three months' notice on either side.

Forms of application may be obtained from the County Medical Officer, County Hall, Boston, by whom they must be received, together with copies of three recent testimonials, not later than 10 a.m. on April 11th, 1938.

County Hall, H. C. MARRIS,
Boston, Clerk of the County Council.
March 21st, 1938.

WEST RIDING OF YORKSHIRE MENTAL HOSPITALS BOARD.

APPOINTMENT OF AN ASSISTANT MEDICAL OFFICER.

WADSLEY MENTAL HOSPITAL, near Sheffield.

Applications are invited for the appointment of an Assistant Medical Officer in the Board's service at the above Mental Hospital, at a commencing salary of £350 per annum, rising by annual increments of £25 to a maximum of £450, together with emoluments (board, apartments and laundry) valued at £120 per annum. The Board will allow an extra £50 per annum to the successful candidate who (whilst on this scale) holds or obtains the Diploma in Psychological Medicine, for which this Hospital affords special study facilities.

It will be an advantage if candidates have had at least one year's experience in general medicine after qualification.

The appointment is subject to the provisions of the Asylums Officers' Superannuation Act, 1909, Class 1.

Applications, with copies of not more than two recent testimonials, stating age and full particulars, to reach the Medical Superintendent, West Riding Mental Hospital, Wadsley, Sheffield, 6, not later than April 11th, 1938.

There is no printed form of application.
Board Offices, G. L. BANNER,
Wadsley, Clerk of the Board.
March, 1938.

CITY AND COUNTY OF BRISTOL.
ASSISTANT MEDICAL OFFICER OF HEALTH.

The Council invite applications for a whole-time male ASSISTANT MEDICAL OFFICER OF HEALTH. Age not exceeding 40 years. Salary £500 per annum, rising by annual increments of £50 to £700. The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922. The Diploma of Public Health is essential.

Candidates having experience in refraction work, and who are recognized by the Board of Education as Certifying Officers under Section 55 of the Education Act, 1921, and Section 31 of the Mental Deficiency Act, 1913, will be given special consideration.

Particulars of the duties of the Assistant Medical Officer may be obtained from the undersigned.

Applications, which must be on the form provided for this purpose, should be accompanied by not more than three recent testimonials, and must be received by the undersigned not later than Saturday, April 2nd, 1938. Envelopes should be endorsed "Assistant Medical Officer of Health." Canvassing will disqualify.

JOSIAH GREEN,
Town Clerk.

Council House, Bristol, 1.
March 15th, 1938.

CITY OF YORK.

ASSISTANT MEDICAL OFFICER OF HEALTH (Woman).

The York Corporation invite applications for the above post.

The duties will consist chiefly of Maternity and Child Welfare work, and the successful applicant will be provided with board and residence in the Maternity Hospital. She must have had the necessary experience in Ante-Natal Clinic duties to satisfy the Ministry of Health's requirements and must, therefore, have had postgraduate experience in midwifery. She may be required to perform any other duties as Assistant Medical Officer.

Salary £350 per annum, together with emoluments (board-residence, etc.), valued at £150 per annum. The appointment is for six months in the first instance.

The Medical Officer of Health is Medical Superintendent of the Hospital, and there is a Consultant Medical Officer.

Applications should be made to the undersigned not later than April 9th, giving name, age, address, qualifications (with dates) and experience. Copies of testimonials or references should also be furnished.

P. R. McNAUGHT, M.D., D.Sc., D.P.H.,
Medical Officer of Health and Medical Superintendent, Maternity Hospital,
50, Bootham, York.
March 22nd, 1938.

CITY OF LEICESTER.

RESIDENT MEDICAL OFFICER.

The Health Committee of the City of Leicester invite applications for the position of Resident Medical Officer (male) at their CITY GENERAL HOSPITAL for a period of six months, renewable if satisfactory for a further six months. The successful candidate will be required to commence as soon as possible. Preference will be given to those with, or reading for, higher qualifications.

The hospital is a modern building with 550 beds, four Resident Medical Officers and one Deputy Medical Superintendent. The work that will be required of this Resident Medical Officer will be chiefly medical; there may, however, be some general surgical work. Salary £300 per annum, together with full residential emoluments.

Further particulars of the appointment may be obtained from the undersigned, and applications (on forms supplied) accompanied by copies of three recent testimonials, must be received not later than April 4th, endorsed "R.M.O." addressed to the undersigned.

E. K. MACDONALD,
Medical Officer of Health.
Health Department,
Grey Friars, Leicester.

COUNTY BOROUGH OF WEST HAM.
PLAINSTOW FEVER HOSPITAL.
(210 Beds)

Applications are invited for the post of JUNIOR ASSISTANT MEDICAL OFFICER (male) at the Plainstow Hospital. Salary £300 per annum, together with residence, board and laundry. Preference will be given to candidates who have held a resident appointment in a general hospital. Grad resident appointment in a general hospital. Grad facilities for postgraduate study are available. The appointment is for one year only.

Application forms can be obtained from the Medical Officer of Health, Municipal Health Offices, Romford Road, Stratford, E.15, and should be returned, together with copies of not more than three recent testimonials, to the Town Clerk, Town Hall, West Ham, E.15, not later than April 5th, 1938.

APPOINTMENTS.—Contd.

COUNTY BOROUGH OF ROTHERHAM. MEDICAL SERVICES COMMITTEE. ASSISTANT RESIDENT MEDICAL OFFICER

Applications are invited from fully qualified Medical Practitioners, with the necessary knowledge and experience of hospital work, for the appointment of a full-time Resident Assistant Medical Officer at the Alma Road Hospital, Rotherham, at a salary of £350 per annum, together with the usual emoluments.

Candidates must be medical practitioners of at least one year's standing, and have held a resident appointment in general hospital or municipal hospital for at least six months.

The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination as to physical fitness.

The appointment will be made for a period not exceeding 12 months.

Forms of application can be obtained from the Medical Officer of Health, Town Hall, Rotherham. Applications, with copies of not more than three recent testimonials endorsed "Assistant Resident Medical Officer," to be sent in to the undersigned not later than April 5th, 1938.

CHAS. L. DES FORGES,

Town Clerk.

Municipal Offices, Rotherham.

March 22nd, 1938

ROYAL LONDON OPHTHALMIC HOSPITAL (MOORFIELDS EYE HOSPITAL), City Road, E.C.1.

Applications are invited for the post of **OUT-PATIENT OFFICER**, to attend on Wednesdays and Saturdays (mornings) each week. Candidates must be registered medical practitioners.

Salary at the rate of £100 per annum. The Out-Patient Officer will be appointed for a period of one year, and will be eligible for re-appointment. Copies of regulations can be obtained on application.

Applications, with testimonials, stating age and qualifications, together with photograph, must be received by the undersigned not later than April 2nd, 1938.

A. J. M. TARRANT, Secretary.

THE NATIONAL TEMPERANCE HOSPITAL, Hampstead Road, London, N.W.1.

Applications are invited for the following post: **CASUALTY OFFICER (male)**. Salary £120 per annum, board, residence and laundry allowance.

The appointment is for a period of six months as from April 1st. Preference will be given to those who have held resident posts.

Candidates must submit applications, stating qualifications, age, etc., with copies of not more than three testimonials, by Monday, March 28th, addressed to the Secretary.

Milk can be monotonous

to the patient who is on a liquid
diet, as the medical practitioner
well knows.

There is a delicious
alternative!

Allenburys Diet

A preparation which, made from full-cream milk and whole wheat, has a more varied composition than that of milk, is made easily assimilable by partial digestion during manufacture, and has an attractive flavour. This delicate flavour may be varied by the addition of Coffee, Cocoa, etc., if required.

In Tins at 2/1, 4/-, and 7/6
